مقدمة أطلس الأجنة

هذا الأطلس يشتمل على أهم الصور الموضحة لعلم الأجنة في الحيوانات المختلفة والإنسان مما يجعله مناسباً لكليات العلوم والزراعة والطب البيطري وكليات التربية وغيرها، والكثير من هذه الصور عليه مصطلحات باللغة العربية مما يسهل على الدارسين من العرب فهم محتوى الرسم. ومعظم هذه الرسوم كبيرة الحجم وأضحة التركيب، ومرتبة في تسلسل حسب وضع الحيوان التصنيفي، وتطوره الجنيني مما يسهل فهم هذا العلم، خصوصاً وأن التركيب الجنيني يتغير مع الوقت، وفي مراحله الأولى يتغير في كل ساعة، وقد حاولت أن اختار الصور المهمة والمراحل الأساسية في الحيوانات المختلفة كي أحافظ على عدد الصفحات في الحدود المعقولة، راجية أن يحوز هذا المجهود على رضاء الدارسين، والله الموفق.

مقارنة بين أجنحة بعض الحيوانات الفقارية

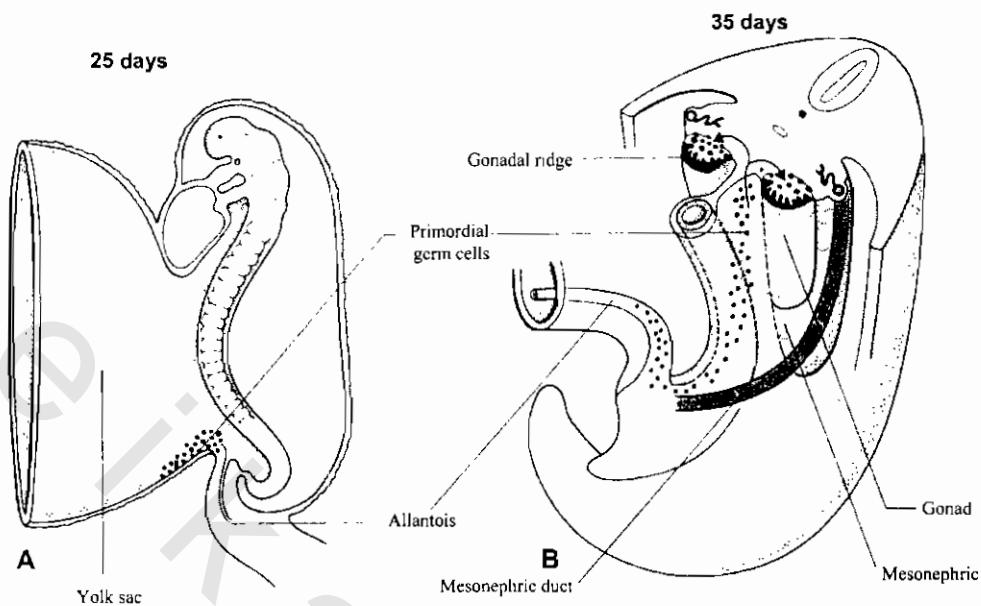

Series of vertebrate embryos in three successive and comparable stages of development. *Top.* All are much alike in the earliest stage. *Middle.* Differentiation is evident, but the four mammals (at right) are quite similar. *Bottom.* Later the distinctive characteristics of each become evident. (After Haeckel, 1891).

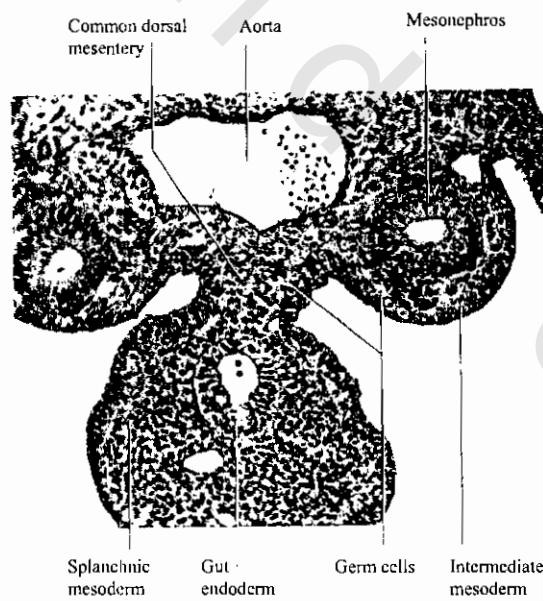

نظريّة التكوين الأزليّ التي عرفت في القرن السابع عشر وتفترض وجود جنين دقيق داخل الحيوان المنوي

Preformation. 17th Century idea of a human spermatozoan
which was supposed to contain a minute embryo. (from Needham, 1959.)

**هجرة الخلايا التناسلية الأولية من الاندوودرم الى داخل المنسل الميوزودرمى
في جنين الانسان في الأسبوع الرابع والخامس من الحمل**

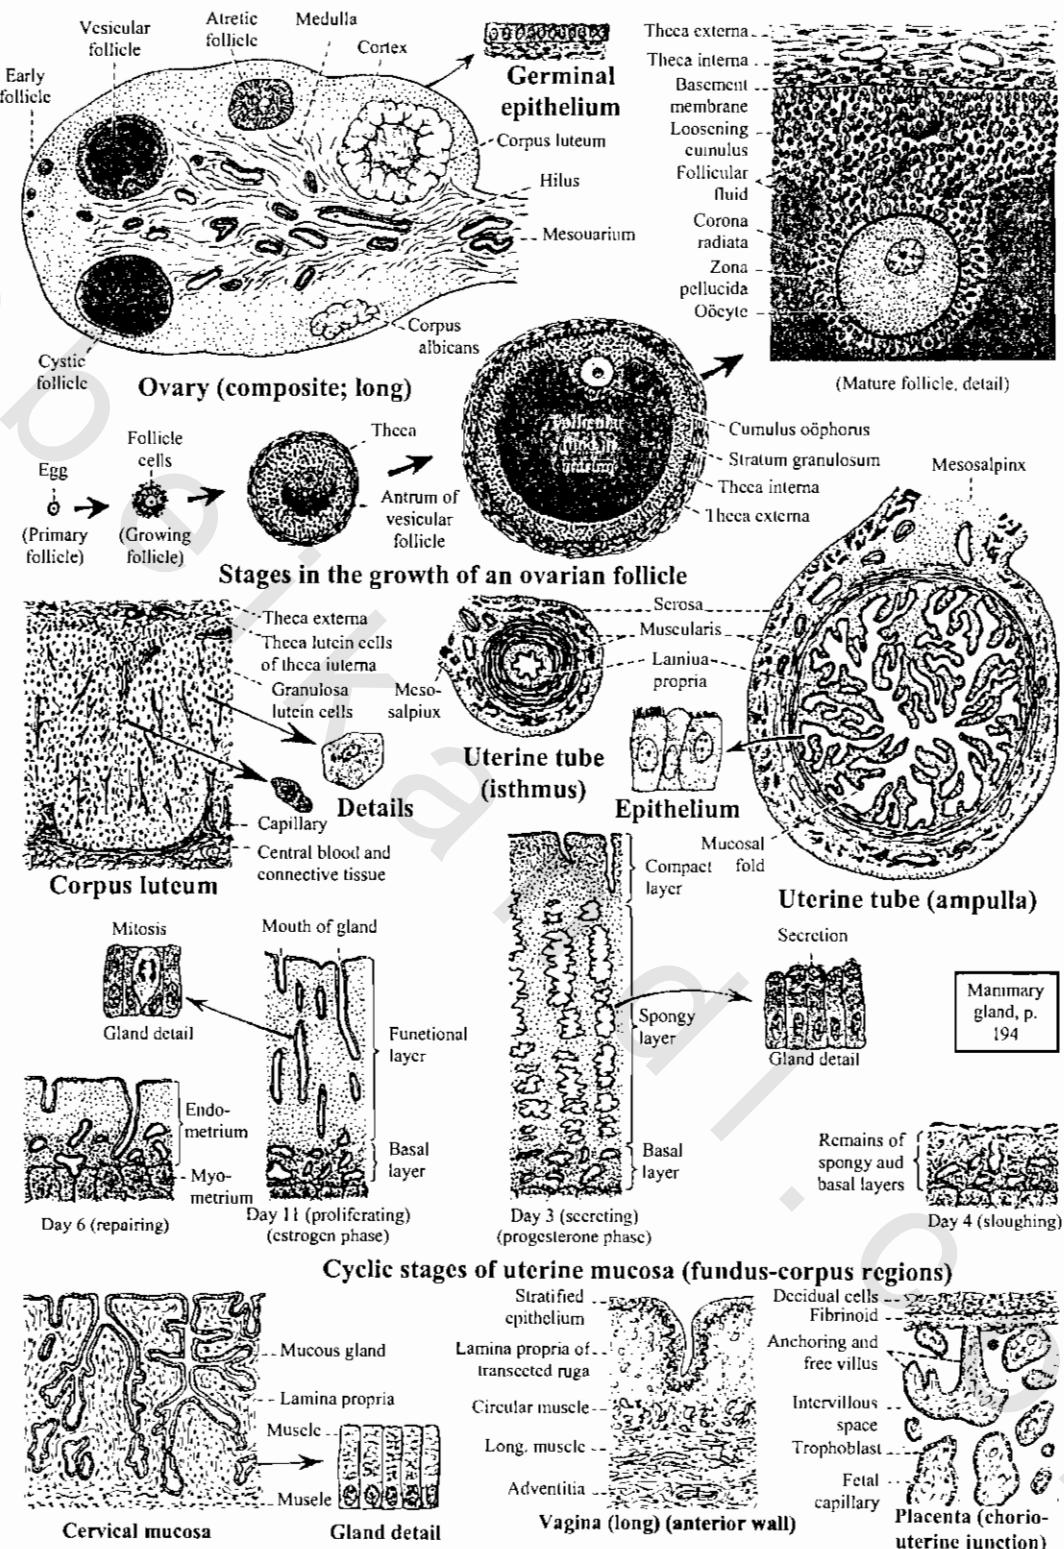

Migration of primordial germ cells during the 4th and 5th weeks. Arrows in (B) denote entry into gonads.

ق. ع. في جنين إنسان عمره خمسة أسابيع يظهر هجرة الخلايا التناسلية إلى المجرى البولي التناسلي

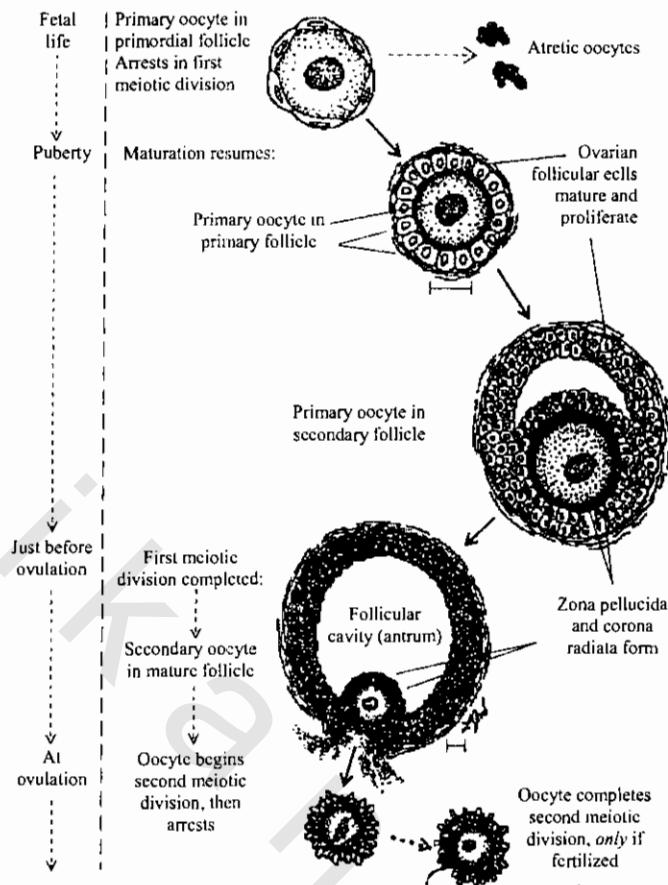

Transverse section of an early 5th – week embryo, showing germ cells traveling to the urogenital ridge.

Maturation of the oocyte and its ovarian follicle.

الأغلفة المحيطة ببعض البويضات الحيوانية
Protective coverings of some animal eggs.

Ovum of a placental mammal. The ovum is a large cell with organelles. The plasma membrane projects as microvilli into the surrounding protein membrane, the zona pellucida. Follicle cells arise from the ovary in which the ovum initially resides

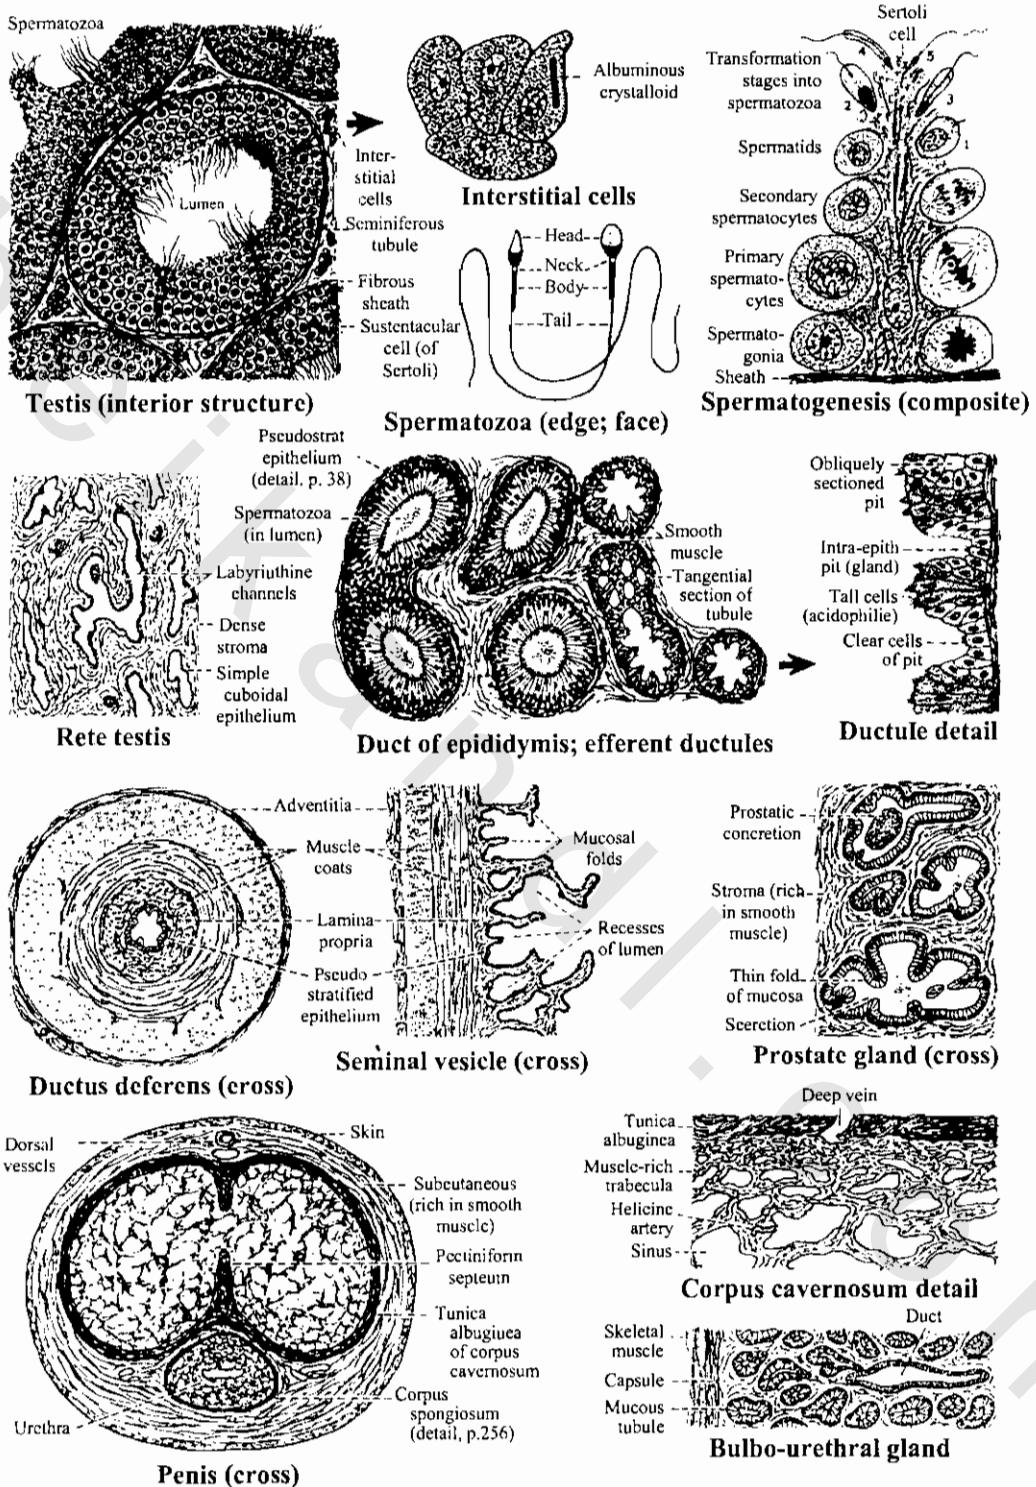

and, depending on the species, they may or may not accompany the ovum at ovulation. Processes of the follicle cells project to the surface of the ovum through the zona pellucida.

تكوين الحيوانات المنوية Spermatogenesis

Seminiferous tubules in the mammalian testis. (a) Schematic diagram of a testis. Each testis is divided into lobules containing seminiferous tubules. These tubules are connected via a network of collecting ducts and the epididymis to the ductus deferens, which joins the urethra. (b) Light micrograph showing partial cross sections of tubules and clusters of interstitial cells in the spaces between them. (c) Drawing of a section of a seminiferous tubule, showing Sertoli cells and germ cells at different stages of spermatogenesis.

تكوين الجاميات Gametogenesis

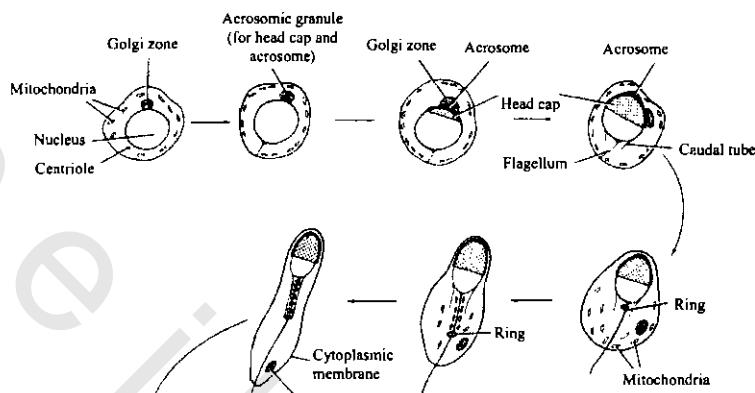

Comparison of spermatogenesis and oogenesis. Primordial germ cells divide mitotically, producing spermatogonia in males and oogonia in females. These cells are diploid, containing two or four genomes (2C or 4C), depending on their stage in the mitotic cycle. Before the gonia enter meiosis, their DNA replicates. They are then called primary spermatocytes or oocytes. After the first meiotic division, they contain two genomes (2C) and are called secondary spermatocytes or oocytes. After the second meiotic division, they are haploid (1C) spermatids or eggs. Note that the two rounds of meiosis produce four haploid spermatids, each of which develops into a spermatozoon, but only one egg results from meiosis of a diploid oogonium; the small polar bodies attached to the egg have no known function.

تفاعل الجسم القمي مع جدار البوية أثناء الإخصاب

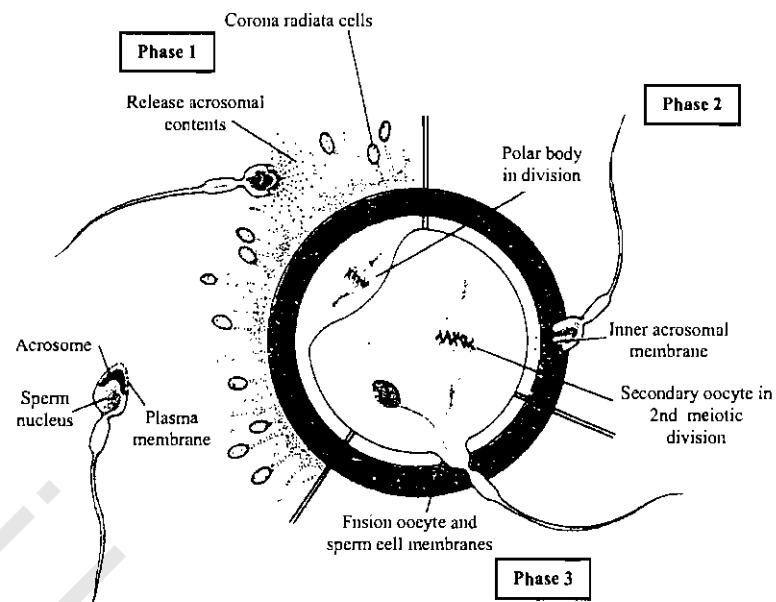

Acrosome reaction in sea urchin sperm. (a) Drawing of the head of an unreacted sperm, showing the nucleus surrounded by the nuclear envelope, the acrosomal material surrounded by the acrosomal membrane, and a subacrosomal space filled with G actin (short lines). The entire sperm is surrounded by the plasma membrane. (b) When the sperm contacts the jelly coat of the egg, the acrosomal vesicle (acrosome) undergoes exocytosis. Proteins (small dots) released from the acrosomal vesicle dissolve the jelly coat. (c) The acrosomal process extends and remains covered with acrosomal material, which adheres to the vitelline envelope. (d) Sperm-egg plasma membrane contact after lysis of the vitelline membrane. Bindin is the substance that enables the sperm to adhere to the egg. (e) Plasma membrane fusion and beginning of sperm entry into the egg.

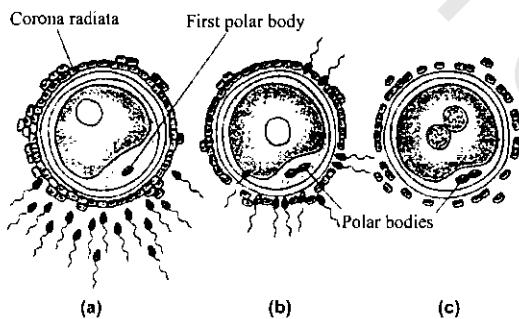

Acrosome reaction in mammals. (a) Transmission electron micrograph of a hamster sperm before the acrosome reaction. A = acrosome. (b) Drawing of sperm head before acrosome reaction, with sperm plasma and acrosomal vesicle intact. (c) During the acrosome reaction, the sperm plasma membrane and the outer acrosomal membrane fuse at many places, forming numerous vesicles. (d) The anterior sperm plasma membrane, visible after the acrosome reaction, is derived from part of the inner acrosomal membrane.

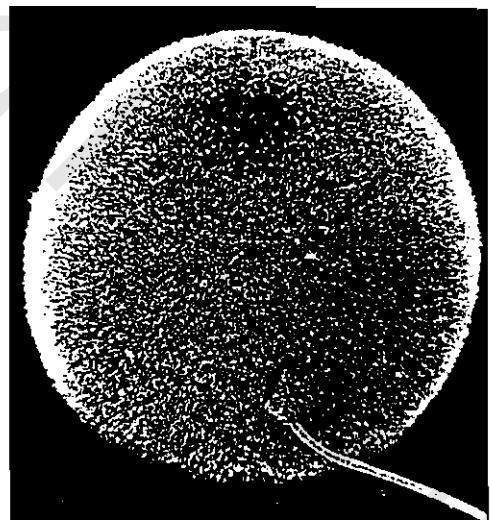

الخصاب | Fertilization

Schematic representation of the three phases of oocyte penetration. In phase 1 the spermatozoa break through the corona radiata barrier; the corona radiata barrier; in 2 phase 2 one or more spermatozoa penetrate in the zona pellucida; in phase 3 one spermatozoon penetrates through the oocyte membrane, thereby losing its own plasma membrane.

Fertilization. (a) Each sperm is thought to release a small amount of enzyme that helps to disperse the follicle cells surrounding the ovum. (b) After a sperm cell enters it, the oocyte completes its second meiotic division, producing an ovum and a polar body. (c) Pronuclei of sperm and ovum combine, producing a zygote with the diploid number of chromosomes. (d) A scanning electron micrograph of a sperm cell fertilizing a hamster ovum. (d, David Phillips/Visuals Unlimited).

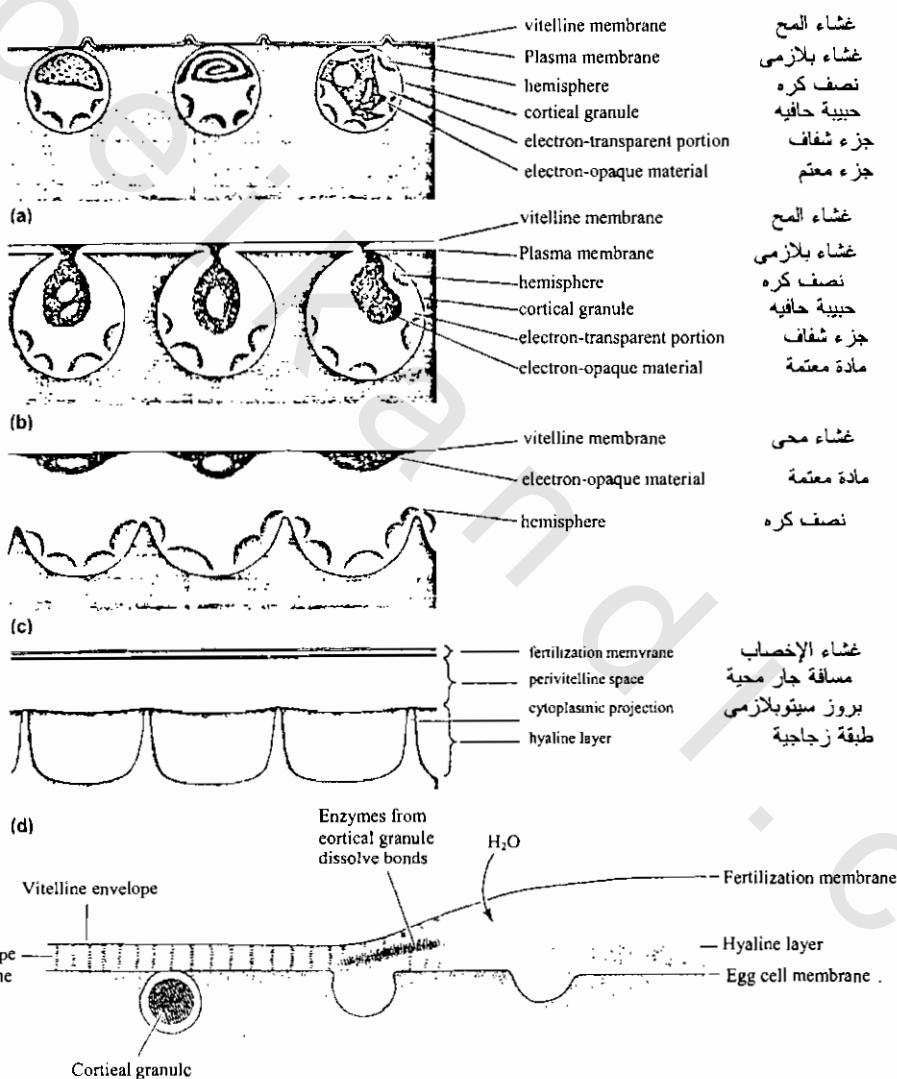

تكوين الحبيبات الحافية

Formation of the cortical granules

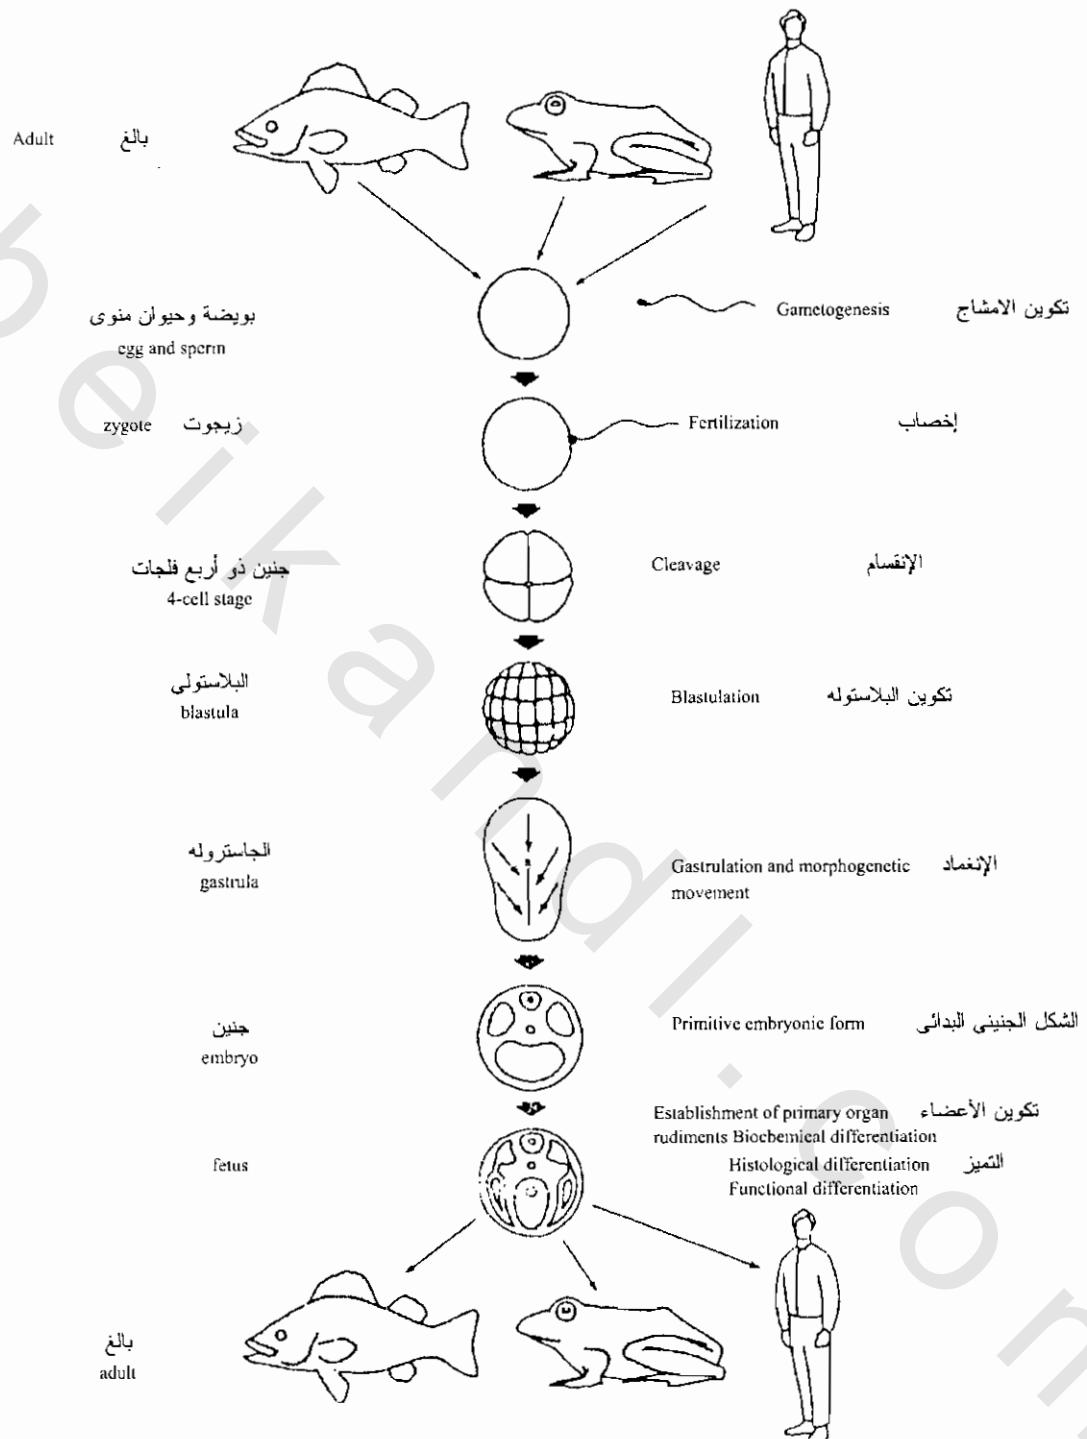

Cortical reaction and fertilization-membrane elevation in the sea urchin

Japonicus. A Unfertilized egg. b Fusion of egg plasma membrane and membrane of cortical granule with beginning of release of granule contents. c Adhesion of electron-opaque material to the vitelline membrane now lifted up; complete fusion of this material with the membrane will give rise to the fertilization membrane. Other material of the cortical granules is expelled into the perivitelline space, while other contents remain close to the egg surface to form the hyaline layer. d The egg surface upon completion of the events. [After Y. Endo, Exp. Cell Res., 25:383 (1961).]

Schematic diagram showing the events leading to the formation of the fertilization membrane and the hyaline layer. As cortical granules burst, they release peptidases, which cleave the bonds joining the vitelline envelope to the cell membrane. Mucopolysaccharides released by the cortical granules form an osmotic gradient, thereby causing water to enter and swell the space between the vitelline envelope and the cell membrane. Other enzymes released from the cortical granules act to harden the fertilization membrane and to release sperm bound to it. (Modified from Austin, 1965.)

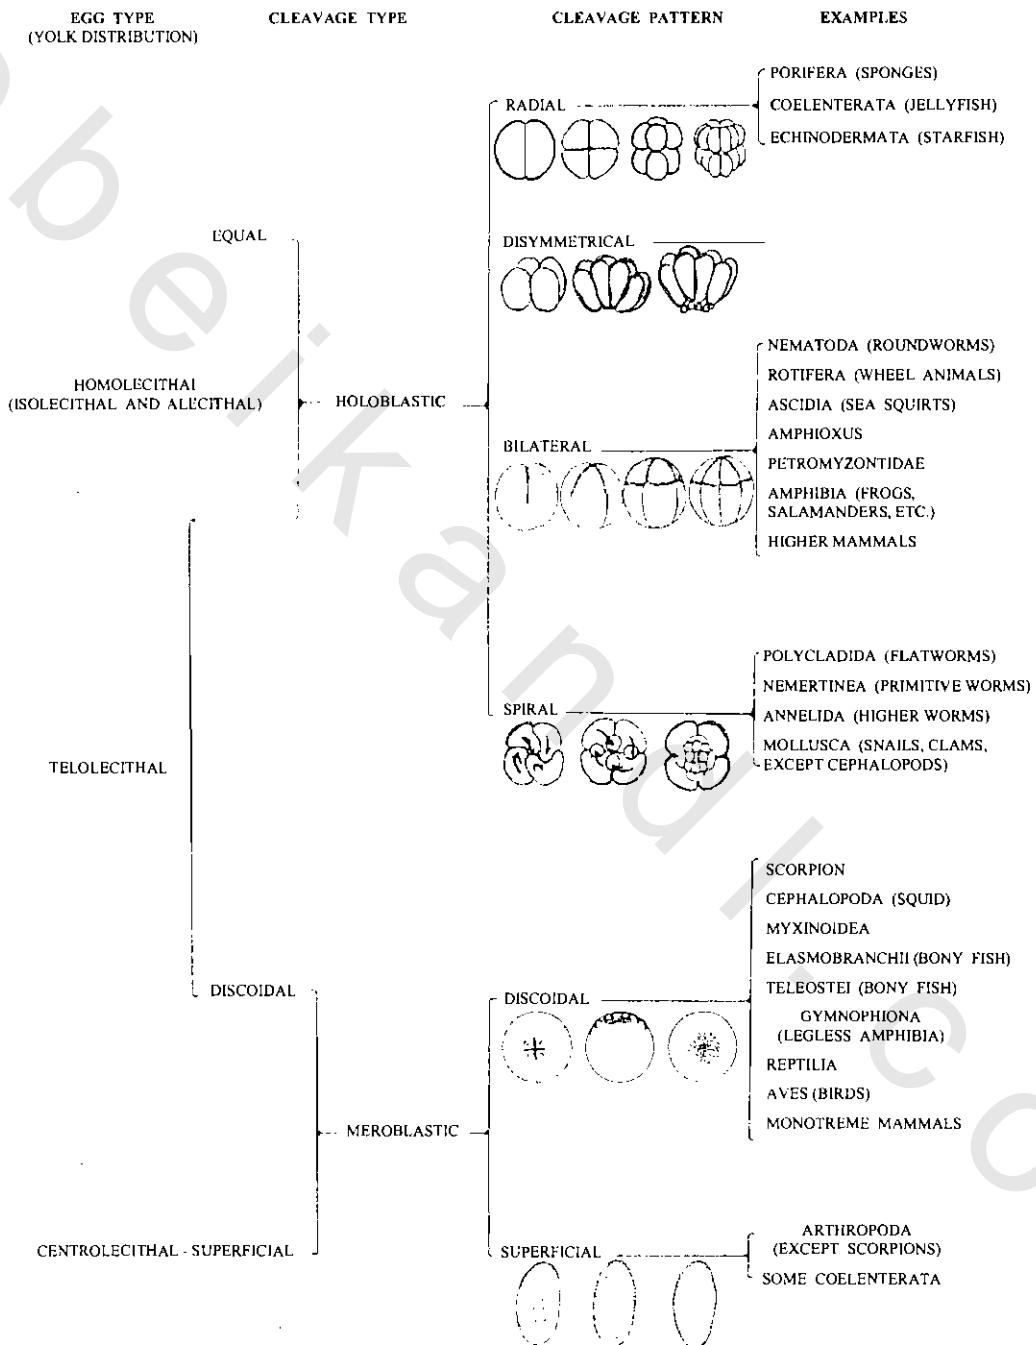

مراحل تكوين الحيوان الفقاري حتى مرحلة النضج الجنسي

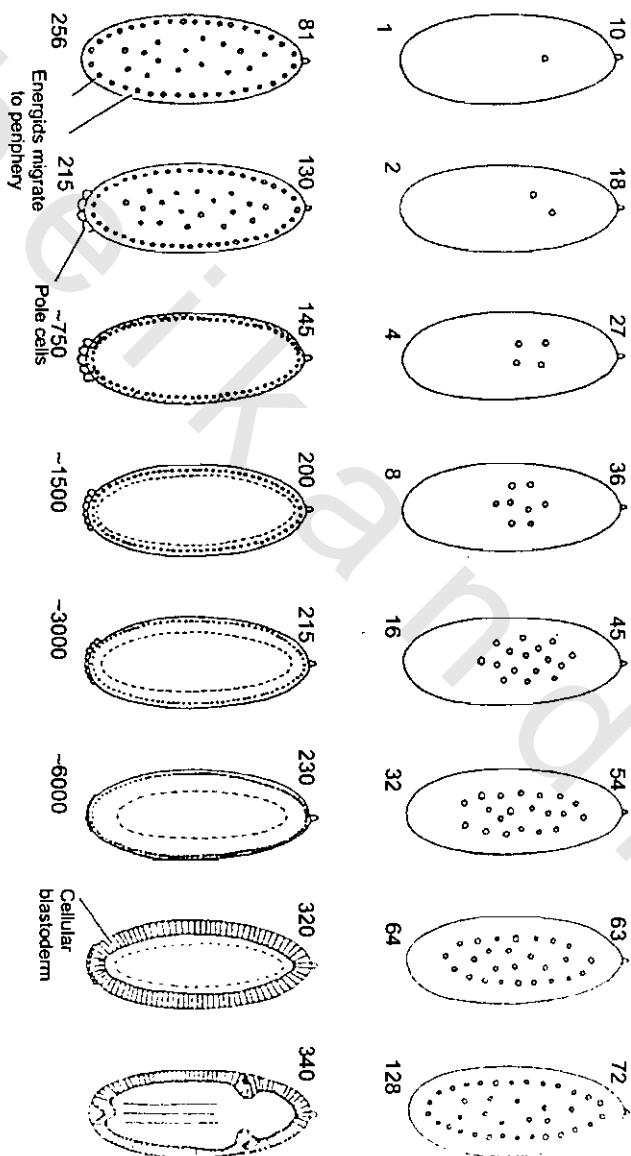

Summary of the common developmental processes
that lead to the formation of adult vertebrate organs

أنماط البيض وأنواع التفليج في الحيوانات المختلفة

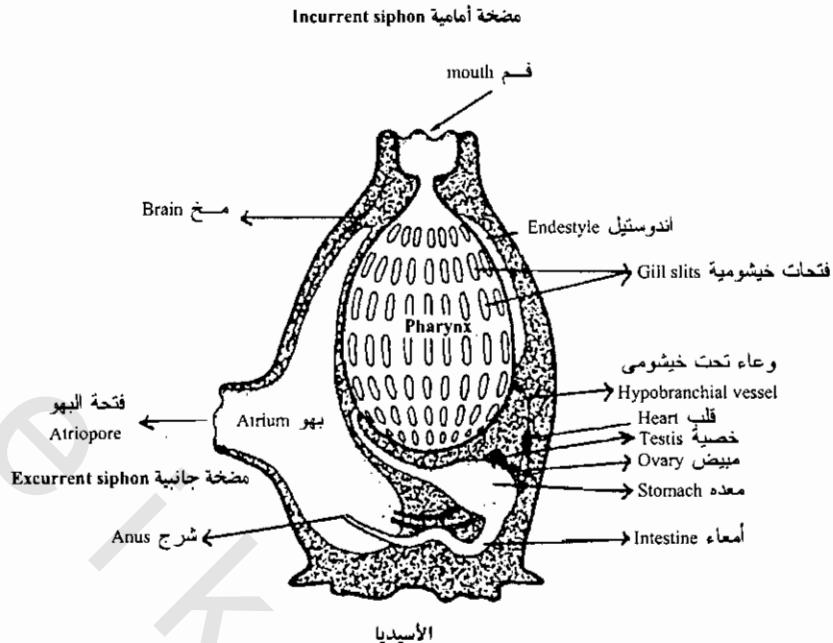

CLASSIFICATION OF EGG AND CLEAVAGE TYPES

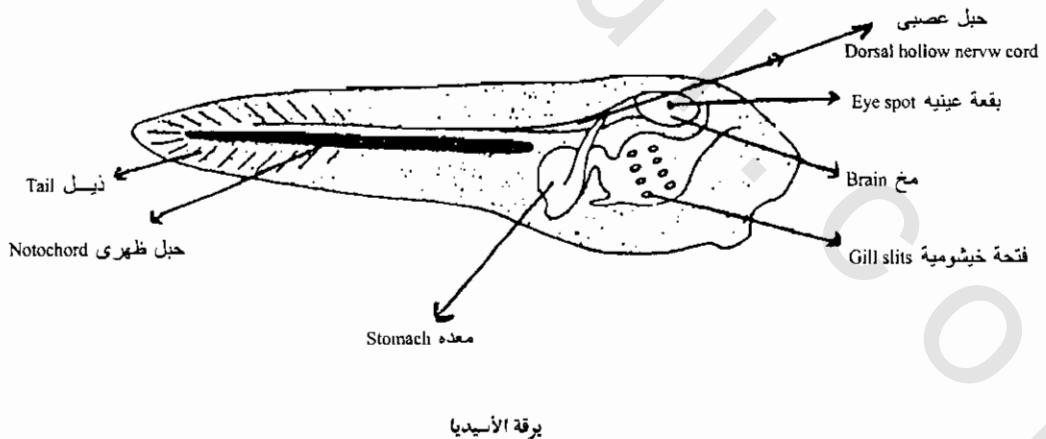

التفلح السطحي في جنين حشرة الدروسوفيلا

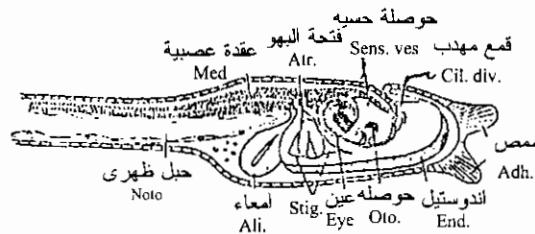

Superficial cleavage in a Drosophila embryo. The numeral above each embryo corresponds to the number of minutes after deposition of the egg; the numeral at the bottom indicates the number of nuclei (energids) present. Pole cells (which will form the germ cells) are seen at the 512-nuclei stage even though the cellular blastoderm does not form until nearly 3 hours later. (Modified from Zalokar and Erk, 1976.)

Mature tunicate. Water and food are taken into the large barrel-shaped pharynx by way of the incurrent siphon. The food is mixed with mucus and enters the stomach; the water moves through the gill slits into the atrial cavity, eventually passing to the outside by way of the excurrent siphon.

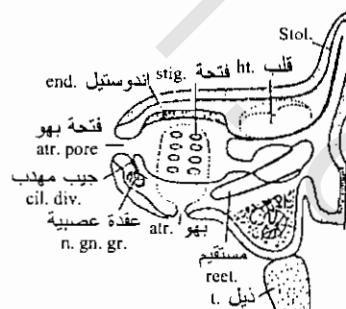

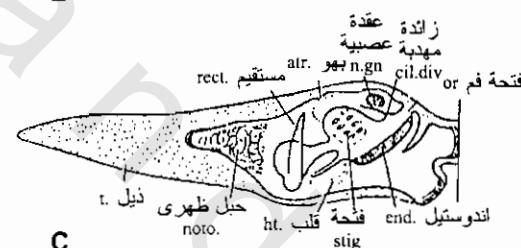

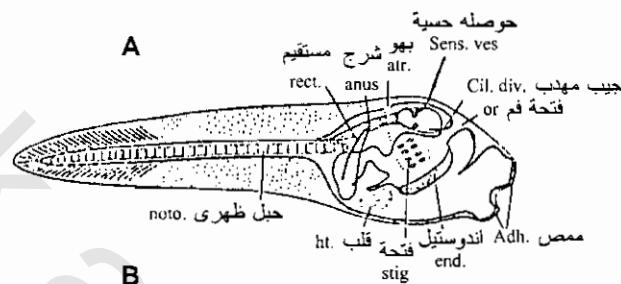

"Tadpole" larva of some tunicates has a tiny brain and a dorsal hollow nerve cord. A notochord is present in the well developed tail and gill slits in pharynx. After swimming about, the larva attaches itself to a suitable substratum. Undergoes metamorphosis, and develops into the sessile adult.

(b) Teleost

Fish ovaries. (a) Hagfish. Oocytes and surrounding follicle cells are held within the ovary. (b) Teleost. Section of the ovary of the guppy *Poecilia reticulata*. Ova are fertilized while they are within the ovary, and they are

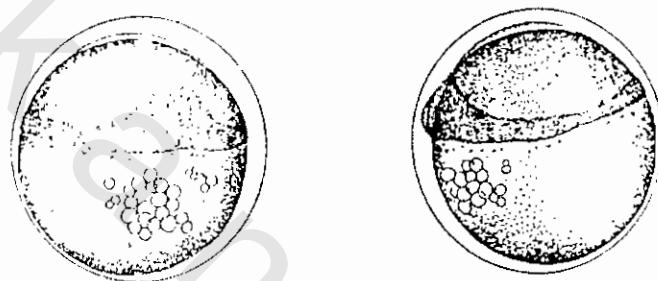

retained well into embryonic development. There can be one to seven oocytes in progressive stages of development. Atretic oocytes that fail to develop and developing embryos are illustrated.

تكوين الجاستروله في الأسماك العظمية

Gastrulation

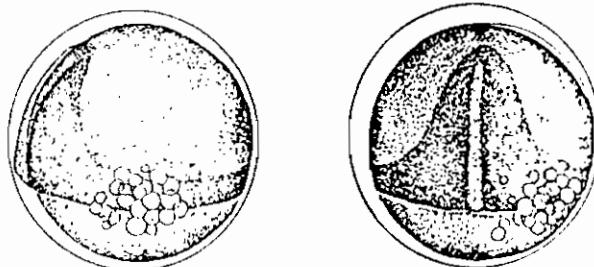

As the blastoderm continues to expand over the yolk, its cells pile up at the periphery at the expense of the centre. The central thin area of the blastoderm is the extra-embryonic membrane which will form yolk sac epithelium. The thickened rim is the germ ring. The thickening of the rim is greater at one portion of the blastoderm. Forming the embryonic shield. This is the region of the future embryo, and it is here that gastrulation begins.

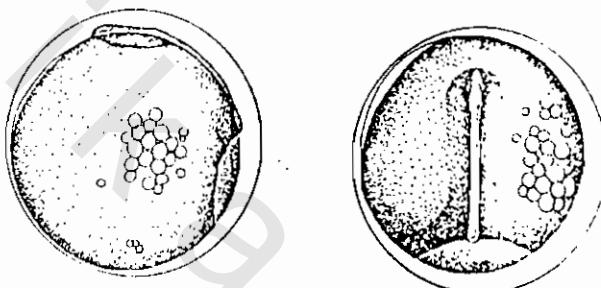

As gastrulation continues, the embryonic shield enlarges by the addition of cells anteriorly, laterally and posteriorly. There is a further accumulation of fine droplets at the vegetal pole, at the future site of the closure of the blastopore.

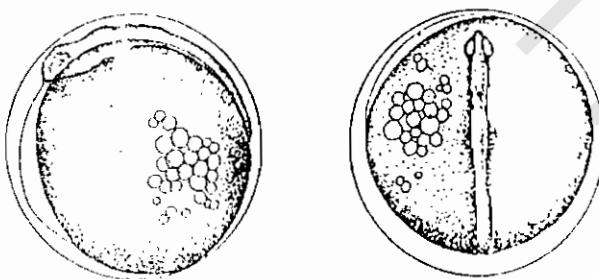

The gastrula has expanded to cover one-half of the yolk. The germ ring is little if any wider but the embryonic shield and axis have extended with epiboly. The latter is about one-sixth the circumference of the egg in length. (A refractive streak of cells is visible in the midline of the shield; this is the solid keel which forms the beginning of the central nervous system.)

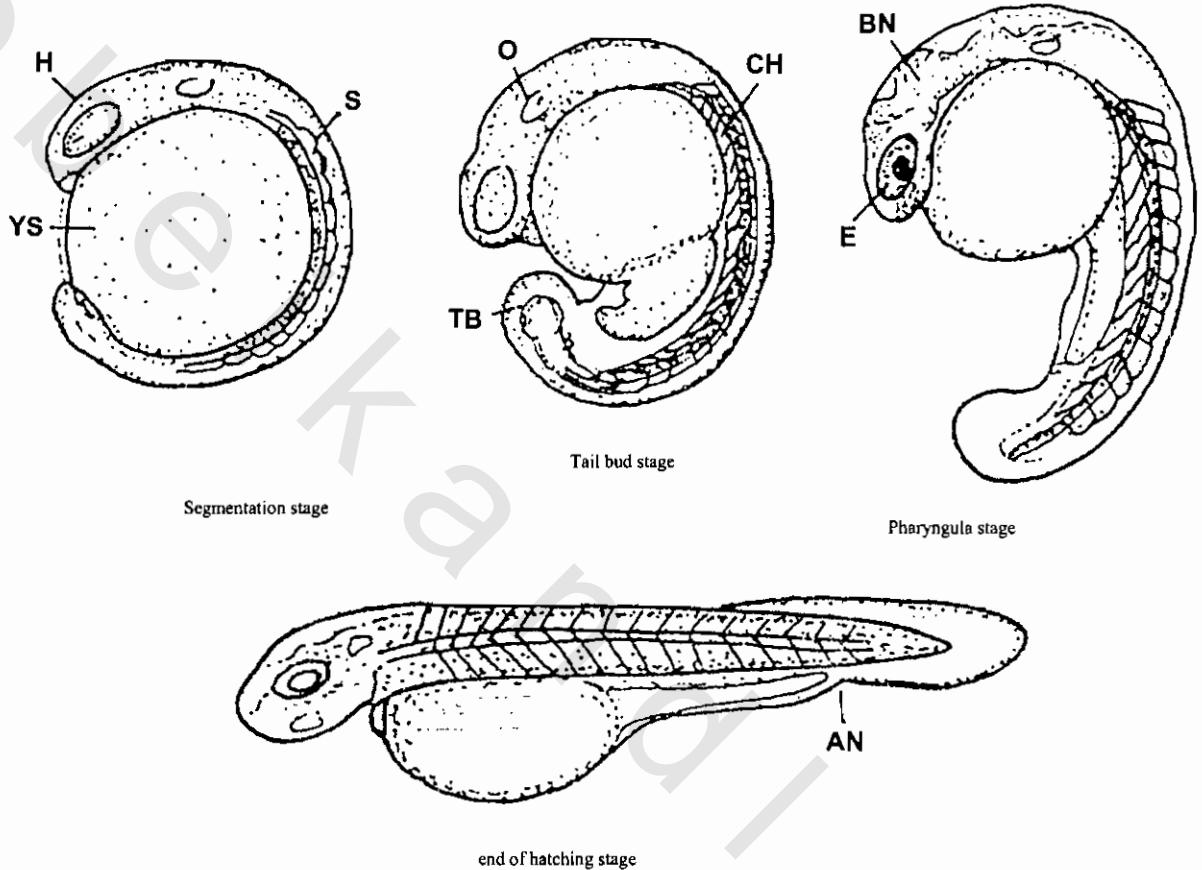

The extra-embryonic ectoderm covers three-fourths of the surface of the yolk. (As the blastoderm continues to expand over the yolk, gastrulation continues, and the shield narrows; the keel of the central nervous system is more clearly marked.)

The blastopore is reduced to a small opening through which the yolk may bulge. The embryonic axis is well defined with some condensation of tissue along its lateral margins. The optic vesicles are present but rudimentary. The embryonic keel is prominent.

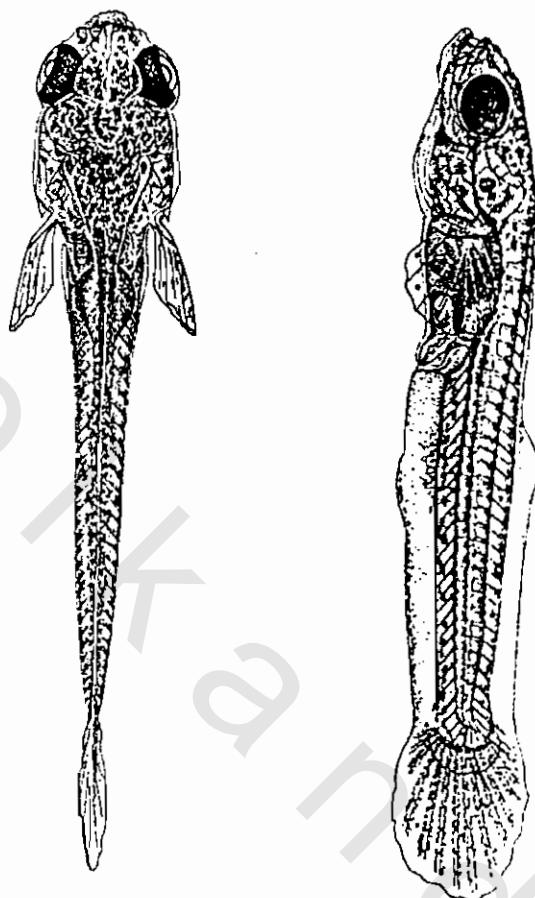

The closure of the blastopore is complete. The main divisions of the brain, the forebrain, midbrain, and hindbrain, are distinguishable with a well defined keel, ventral to the brain, indenting the yolk sac. There is an increased but variable condensation of cells lateral to the embryonic axis in the location of the future anterior somites. Kupffer's vesicle appears as the embryos advance towards the next stage. The ectoderm lifts to form a large vesicle anterior to the head, possibly the forerunner of the pericardial cavity.

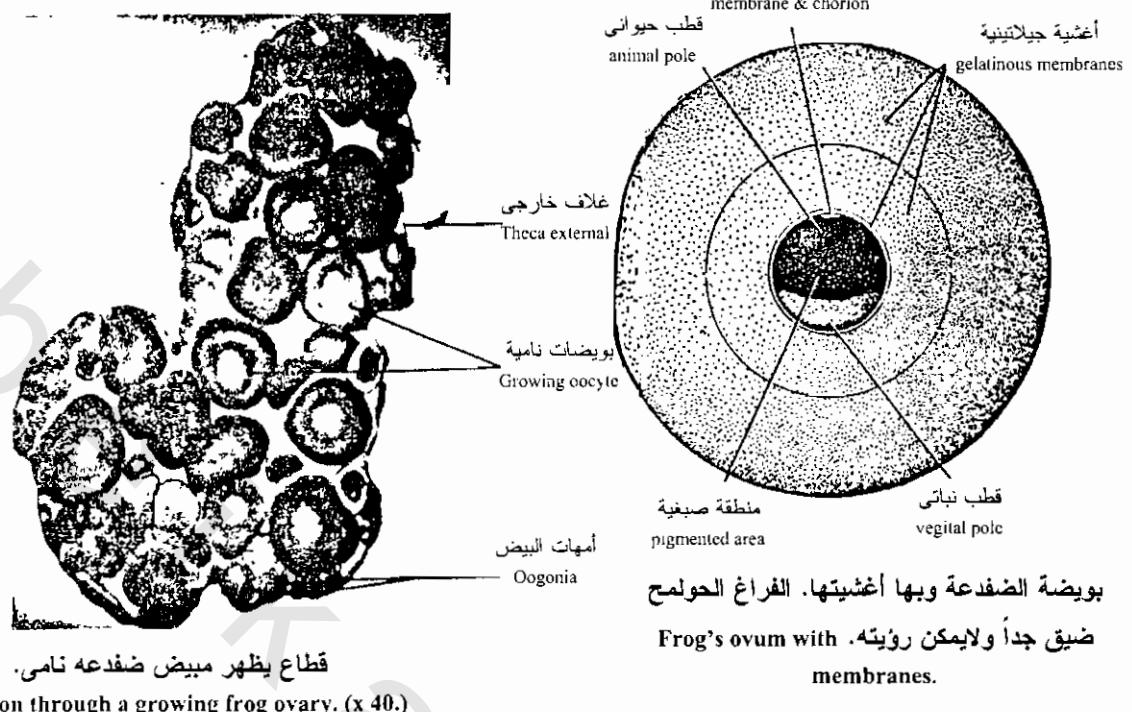

رسوم تخطيطية توضح مراحل مختلفة من التكوين الجنيني المتأخر في سمكة الشبوط
Schematic diagrams illustrating various stages of the embryonic development of silver carp.

مرحلة وسطية بين الجنين واليرقة في سمكة عظمية

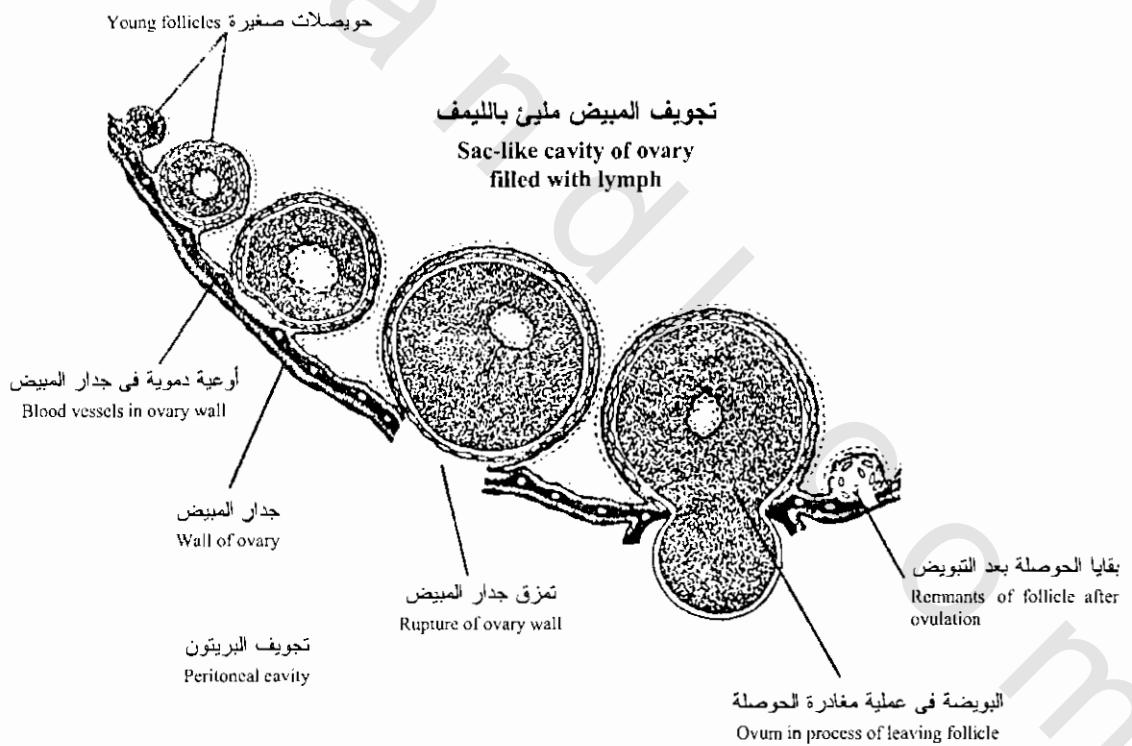

This is a transition stage from the embryonic to the larval state with the complete absorption of the yolk. The operculum and pectoral fins are almost continuously rhythmically active. The swim bladder has increased in size and the embryos commonly swim at the surface of the water, but will swim to the bottom of the aquarium if disturbed, the pectoral fins being in constant motion. (The designation of the stage where the yolk is absorbed as the final step of the series is purely arbitrary; it must not be thought that at this stage the fry are miniature adults. Many more changes must ensue before adult proportions are attained: skin and scales must be differentiated, much of the skull and axial skeleton remains to be elaborated, the definitive pigment pattern is yet to be laid down, and the anal fins are still to be formed, to mention only a few of these changes. In addition the body as a whole is to undergo considerable change of proportion, and its parts varying degrees of heterogonic growth. Since all these processes are gradual and a continuation of the earlier processes described, there can be chosen no exact moment when the embryo metamorphoses into an adult. The stage of yolk absorption is a convenient stopping place because the primitive organ systems are all represented at this stage.)

A section through an amphibian ovary

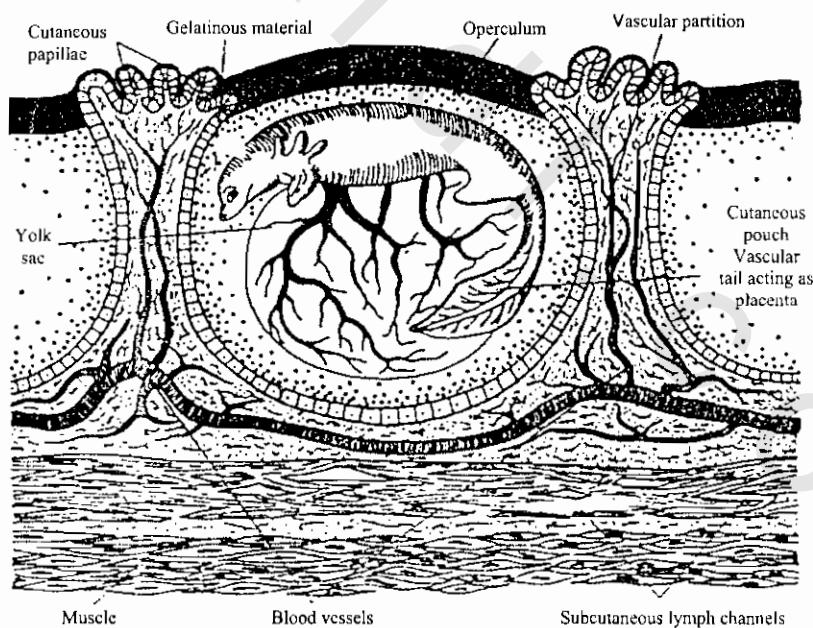

الإخصاب
Fertilization

Fertilization of a frog's egg occurs in shallow water. When a sperm (1) from the male penetrates the egg, the second polar body (2) forms. The sperm leaves a trail (3) caused by the displacement of granules in a layer of pigment. The nuclei of the sperm and egg fuse, forming a zygote (4). Penetration by the sperm induces a shift in the pigment layer, resulting in the formation of a gray crescent (5) opposite the point of entry, which determines the first line of cleavage (6). Successive divisions (7) form a ball of cells.

Anura: Ovoviparity. In the Surinam Toad (*Pipa dorsigera*) the eggs are lodged in lidded pits in the dorsal surface of the female. (After Mivart.)

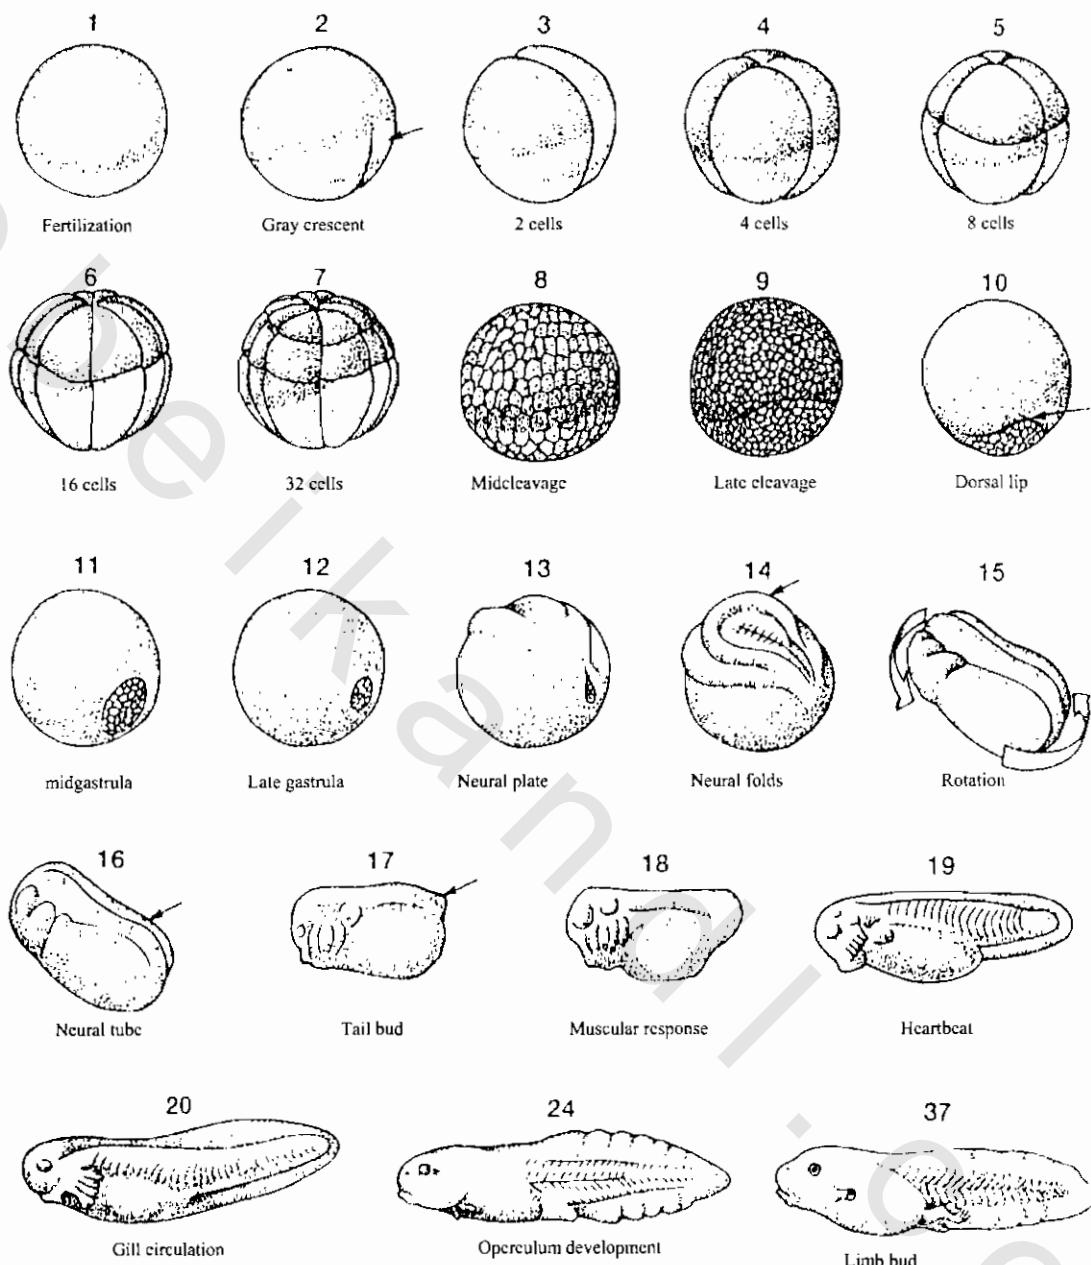

ضفدع سورينام البيوضة الولودة حيث تحفظ الأنثى بيضها، في حفر ظهرية ذات غطاء، حتى يفقس

Anura: Pseudo-placenta. Gaseous exchanges occur between the maternal tissues and the expanded, leaf-like tail of the pouch larva of *Pipa dorsigera*. (After Amoroso).

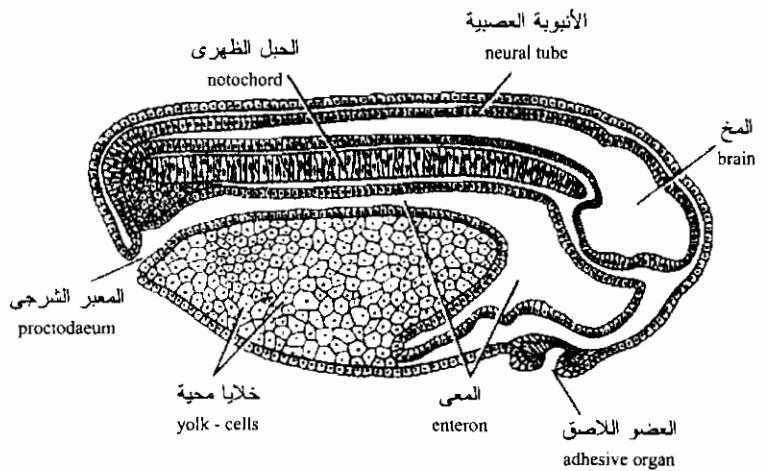

المشيمة الزائفة في البرمائي اللازيلى المسمى بببا حيث يحدث تبادل في الغازات بين الأوعية الدموية للأم وتلك الموجودة في ذيل الجنين الورقى الشكل

مناظر خارجية لتكوين البرمائيات الالاذيلية

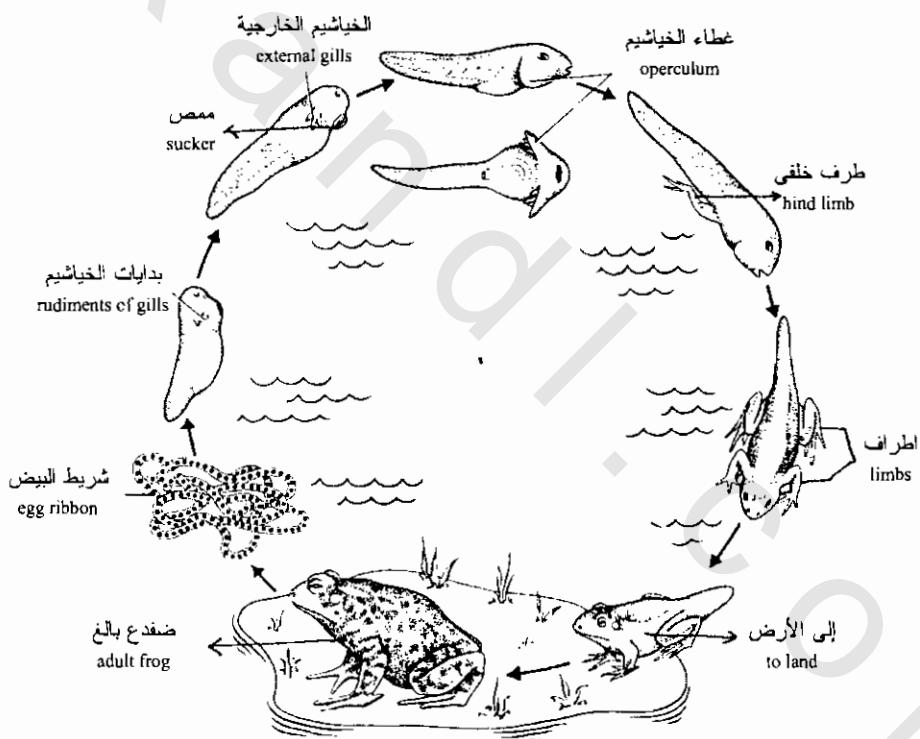

External view of anuran development. Beginning with fertilization (1), morula (6-8), blastula (9 and 10), gastrula (11 and 12), and neurula (13-16) stages follow successively. In later development, the tail bud forms (17), muscular twitches begin (18), heartbeat commences (19), functional external gills develop (20), and blood circulation

occurs through the caudal fin. Subsequent events include the formation of an operculum (24), a flap of head skin that grows over and covers the gills. The hindlimbs develop first and then the forelimbs. Eventually the embryo undergoes metamorphosis into a juvenile frog. Stages between 20-24 are not illustrated.

الجهاز التناسلي الانثوي في الدجاجة

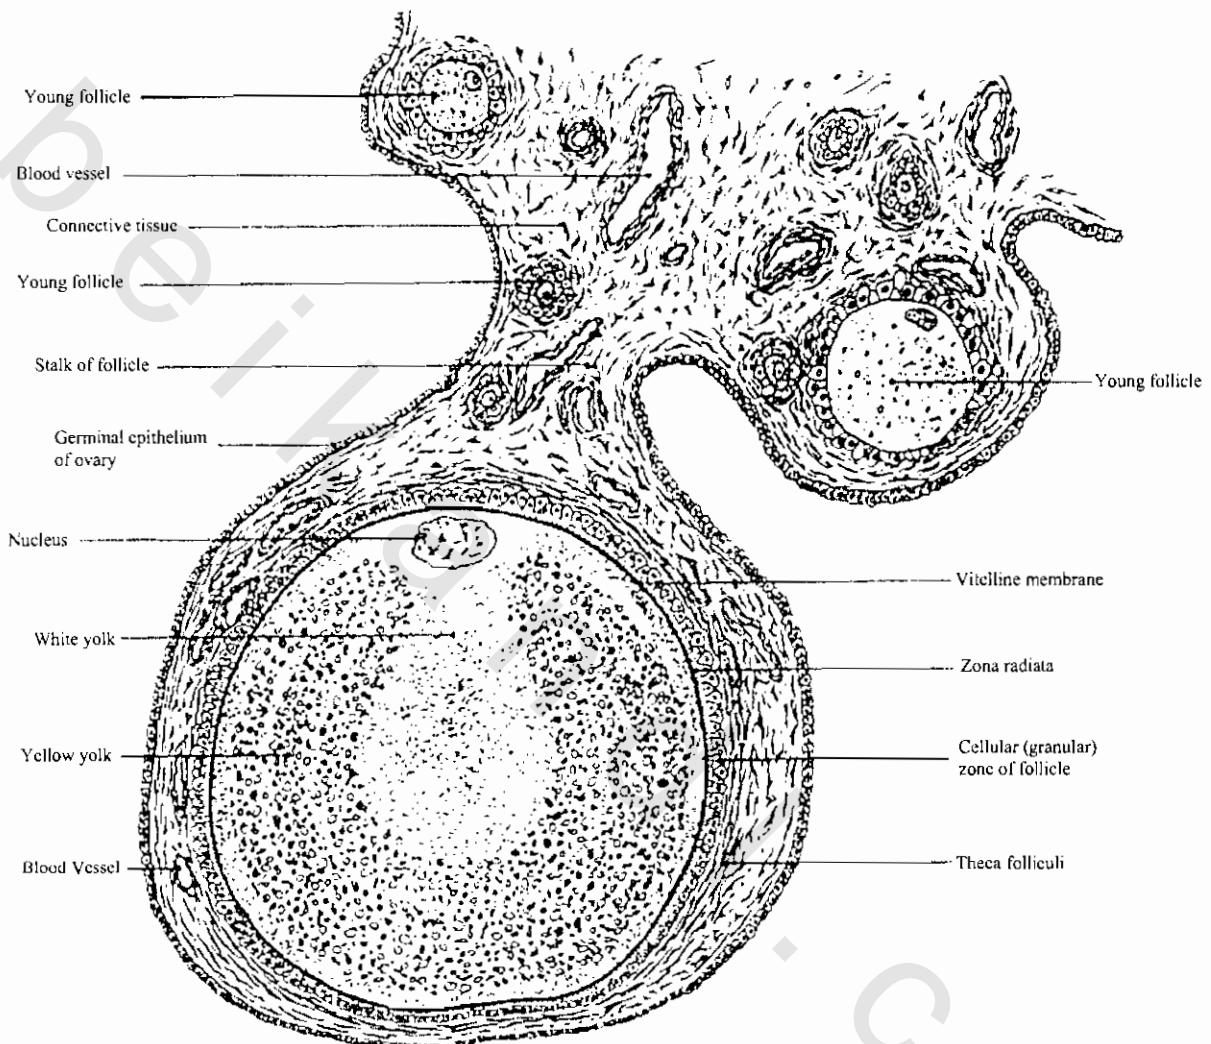

The female reproductive system of the fowl (After Coste-Duval.) The figure shows two eggs in the oviduct, though normally only one is in the oviduct at a time. A, albumen (dense layer); B, blastoderm; C, cicatrix; cl, cloaca; F, follicle from which egg has been discharged; G, Glandular portion of oviduct, I, isthmus; O₁-O₄, ovarian ova in different stages of growth, each enclosed in a follicle richly supplied with blood vessels; O₁, ovum in upper end of oviduct; O₂, ovum in middle portion of oviduct, which has been cut open to show the ovum in position; Os, ostium (infundibulum) of oviduct; Ov, ovary, R, rectum, U, uterus. (From H. L. Wieman, *An Introduction to Vertebrate Embryology*. Copyright 1949 by McGraw-Hill Book Co. Used with permission of McGraw-Hill Book Co.)

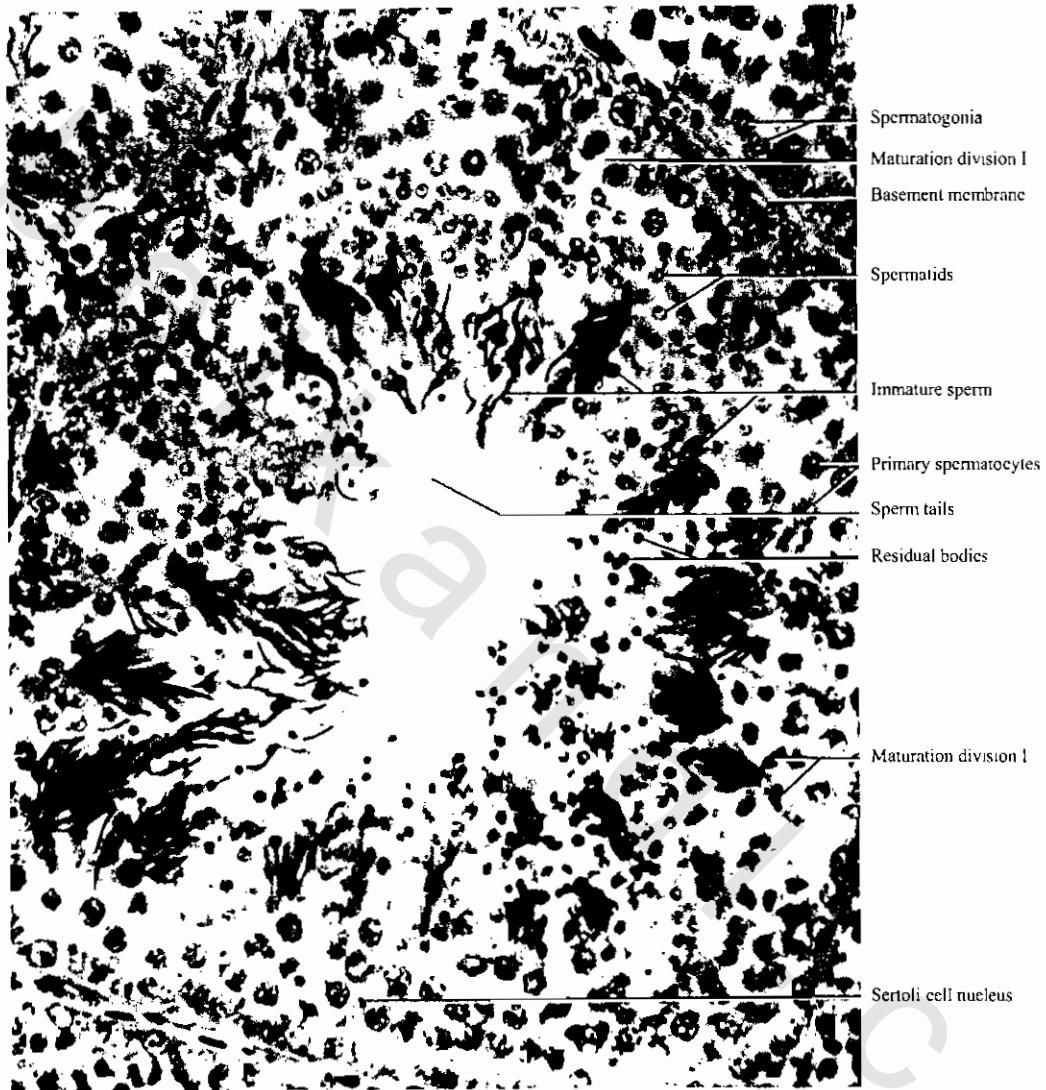

تركيب بيضة الدجاجة عند خروجها من الجسم

Growth and composition of hen's Egg before incubation. (Weight curve of ovocyte during 18 days preceding laying, after Gerhardt 1914.) The cells of the blastoderm are drawn relatively too large in size and too few in number. White yolk is lightly stippled, yellow yolk is heavily stippled (the central white yolk is called latebra of Purkinje, that below the blastoderm nucleus of Pander). Egg yolk, being relatively lighter than egg white, tends to float toward the highest part of the shell. (From *Development of the Vertebrates*, by Emil Witschi. Copyright © 1956 by W. B. Saunders Company. Used with permission of the W. B. Saunders Company, a division of CBS College Publishing.)

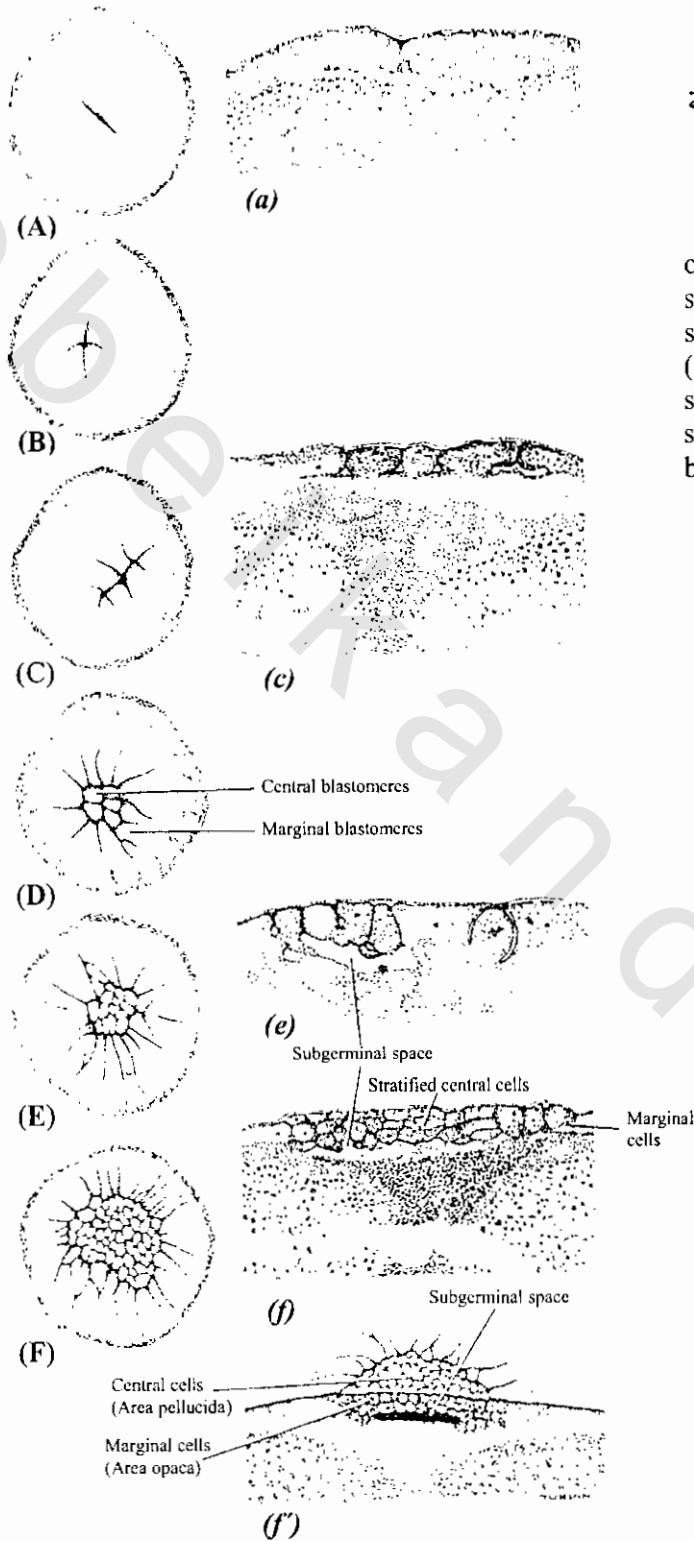

رسم تخطيطي يوضح تركيب البويضة الناضجة داخل المبيض

Diagram showing the structure of a bird ovum still in the ovary. (Modified from Lillie, after Patterson.) The section shows a follicle containing a nearly mature ovum, together with a small area of the adjacent ovarian tissue.

ق. ع. في أنبيبة منوية للكنکوت. تکبیر ۶۸۰

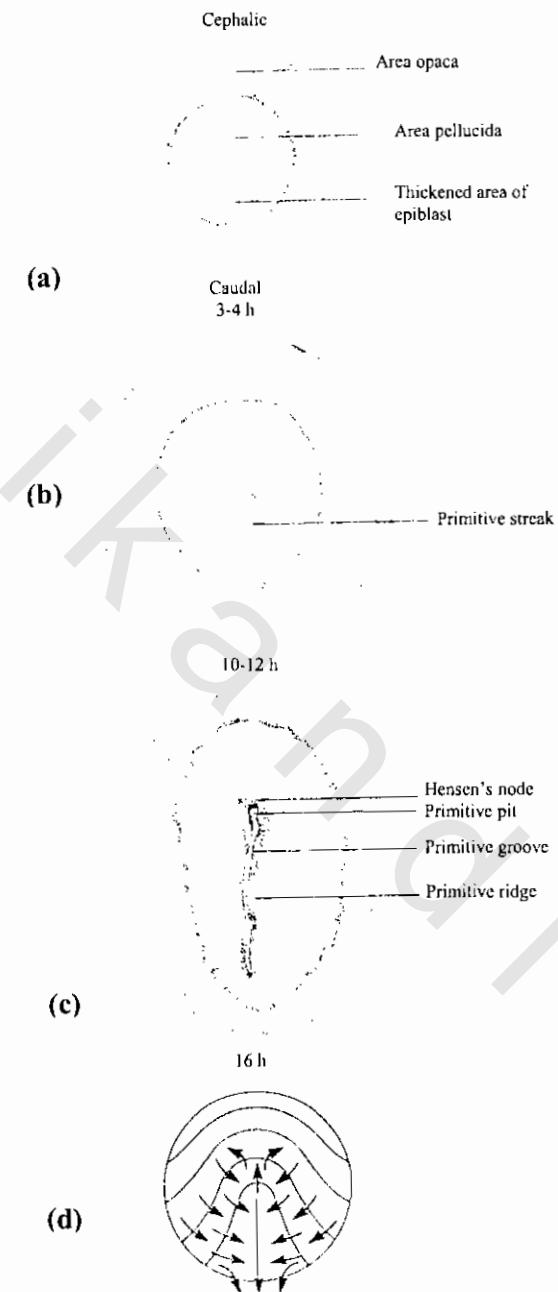

Chicken testis, section (mag. 680X)

التفلج في القرص الجرثومي في جنين الكتكوت
كما يظهر من السطح العلوي أو في قطاعات عمودية

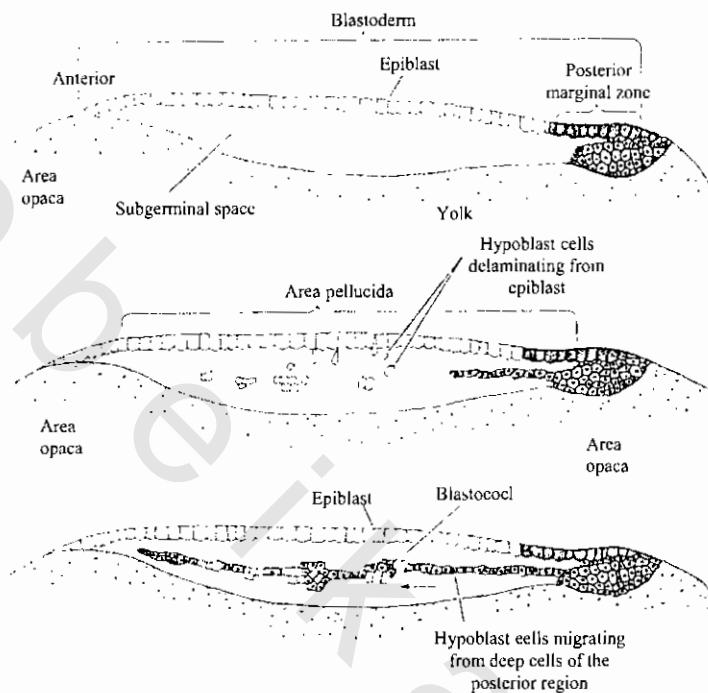

Cleavage of the germinal disc of the ovum of the domestic chicken. Left hand figures are surface views; right hand figures are transverse sections. (After Patterson.) (A, a) 2-cell stage. (B) 4-cell stage. (C, c) 8-cell stage. (D) 16-cell stage. (E, e) 32± cell stage. (F, f) 154± cell stage. (f') Diagrammatic hemisection of blastoderm of 154± cells.

تكوين الشق البدائى فى جنين الكتكوت كما يظهر من السطح الظهرى

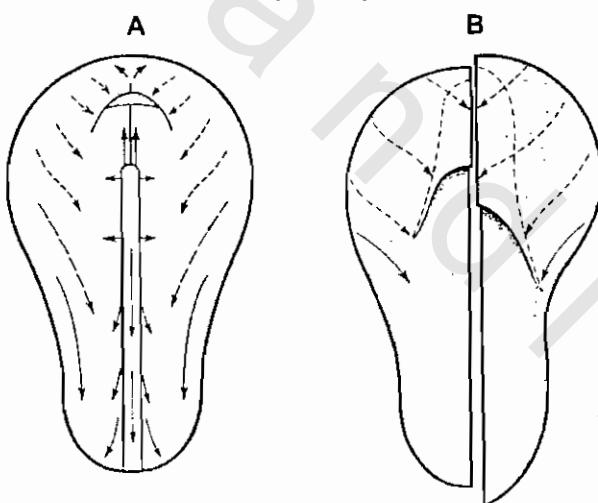

Primitive streak formation in the chicken embryo. All drawings show dorsal views of the epiblast. Most of the large uncleaved yolk has been omitted. (a) 3-4 h incubation. (b) 10-12 h incubation. (c) 16 h incubation. (d) Interpretative diagram of cell movements.

تكوين بلاستوله الكتكوت

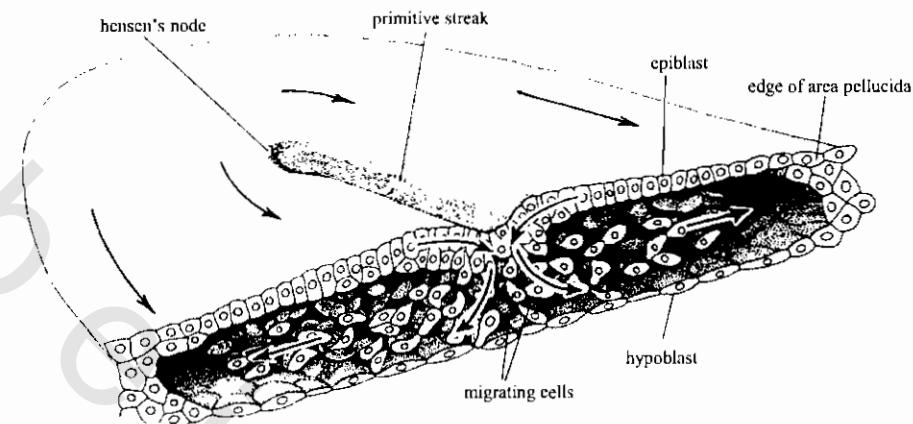

Formation of the two-layered blastoderm of the chick embryo. The first hypoblast cells delaminate individually to form islands of cells beneath the epiblast. Cells from the posterior margin (Koller's sickle and the posterior marginal cells behind it) produce a population of cells that migrates beneath the blastodisc and incorporates the polyinvagination islands. This bottom layer becomes the hypoblast. The upper layer is the epiblast. As the hypoblast moves anteriorly, epiblast cells collect at the region anterior to Koller's sickle to form the primitive streak.

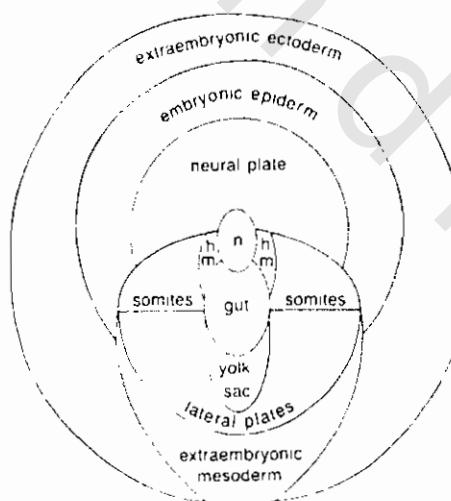

حركة الخلايا الاندودرمية أثناء تكوين المعي الأمامي في جنين الكتكوت

Morphogenetic movements during foregut formation. When labelled cells were followed in the endoderm of the chick embryo, two types of cell movement were found. (a) '2-dimensional', which stayed in the original plane: black arrows; (b) '3-dimensional', which moved ventrally: dotted arrows. A. headfold stage. B. two later stages. Both A and B are viewed from the ventral (endodermal) side. (From Bellairs, 1953.)

النصف الأمامي من المنطقة الشفافة ومقطع عرضي بها يظهر إنعامد الخلايا الميزودرمية والأندودرمية

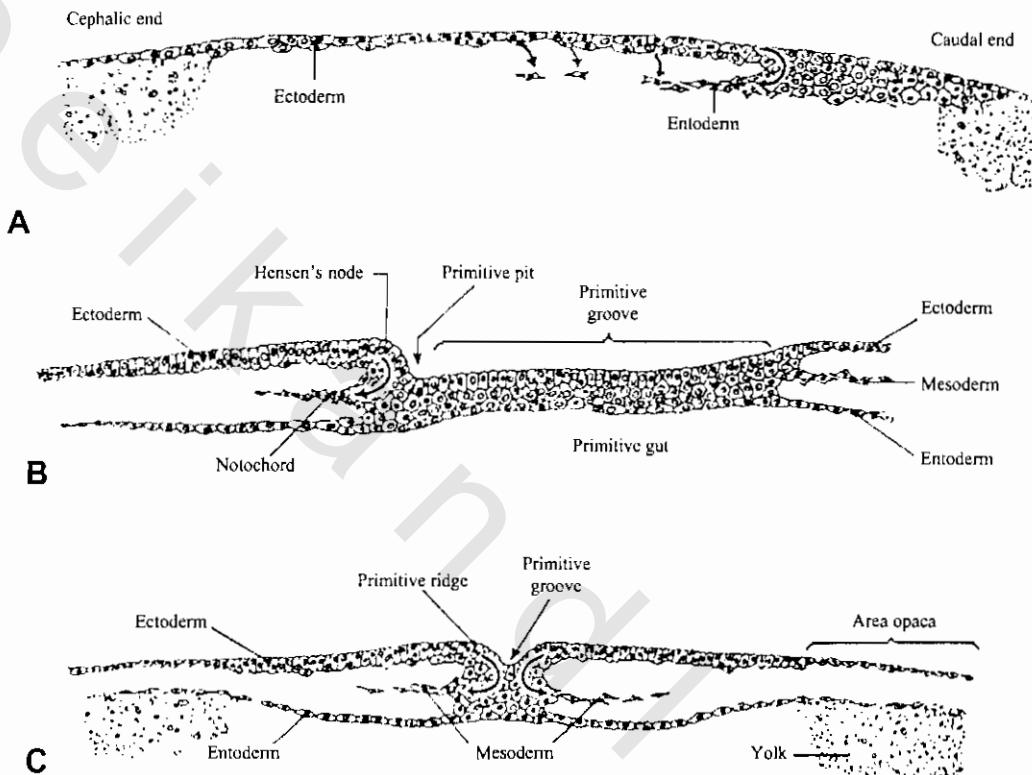

Anterior half of the area pellucida of a chick embryo cut transversely to show the migration of mesodermal and endodermal cells from the primitive streak. (From An Introduction to Embryology, 5th edition, by B. I. Balinsky, assisted by B. C. Babian. Copyright © 1981 by CBS College Publishing. Reprinted by permission of W. B. Saunders, a division of CBS College Publishing.)

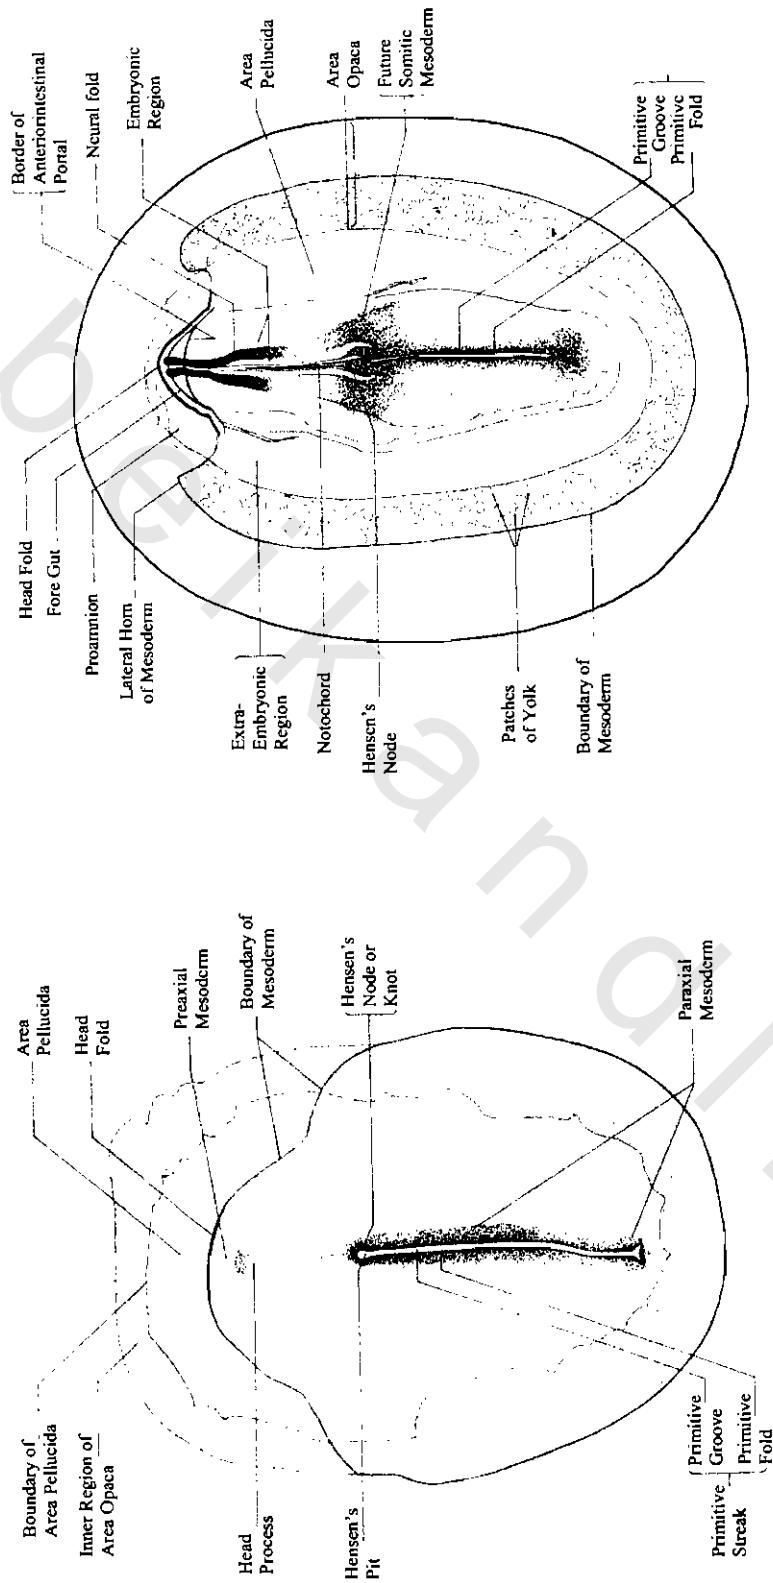

خريطة المصير لجنين الدجاجة في بداية مرحلة التبطين

Fate map of the chick embryo at the beginning of gastrulation. (Based on the experiments of G. C. Rosenquist and G. Nicolet.) n, notochord; hm, head mesenchyme. (From An Introduction to Embryology, fifth edition by B. I. Balinsky, assisted by B. C. Babian. Copyright © 1981 by CBS College Publishing. Reprinted by permission of W. B. Saunders, a division of CBS College Publishing.)

حركة الخلايا أثناء التطبيخ في جنين الكتكوت

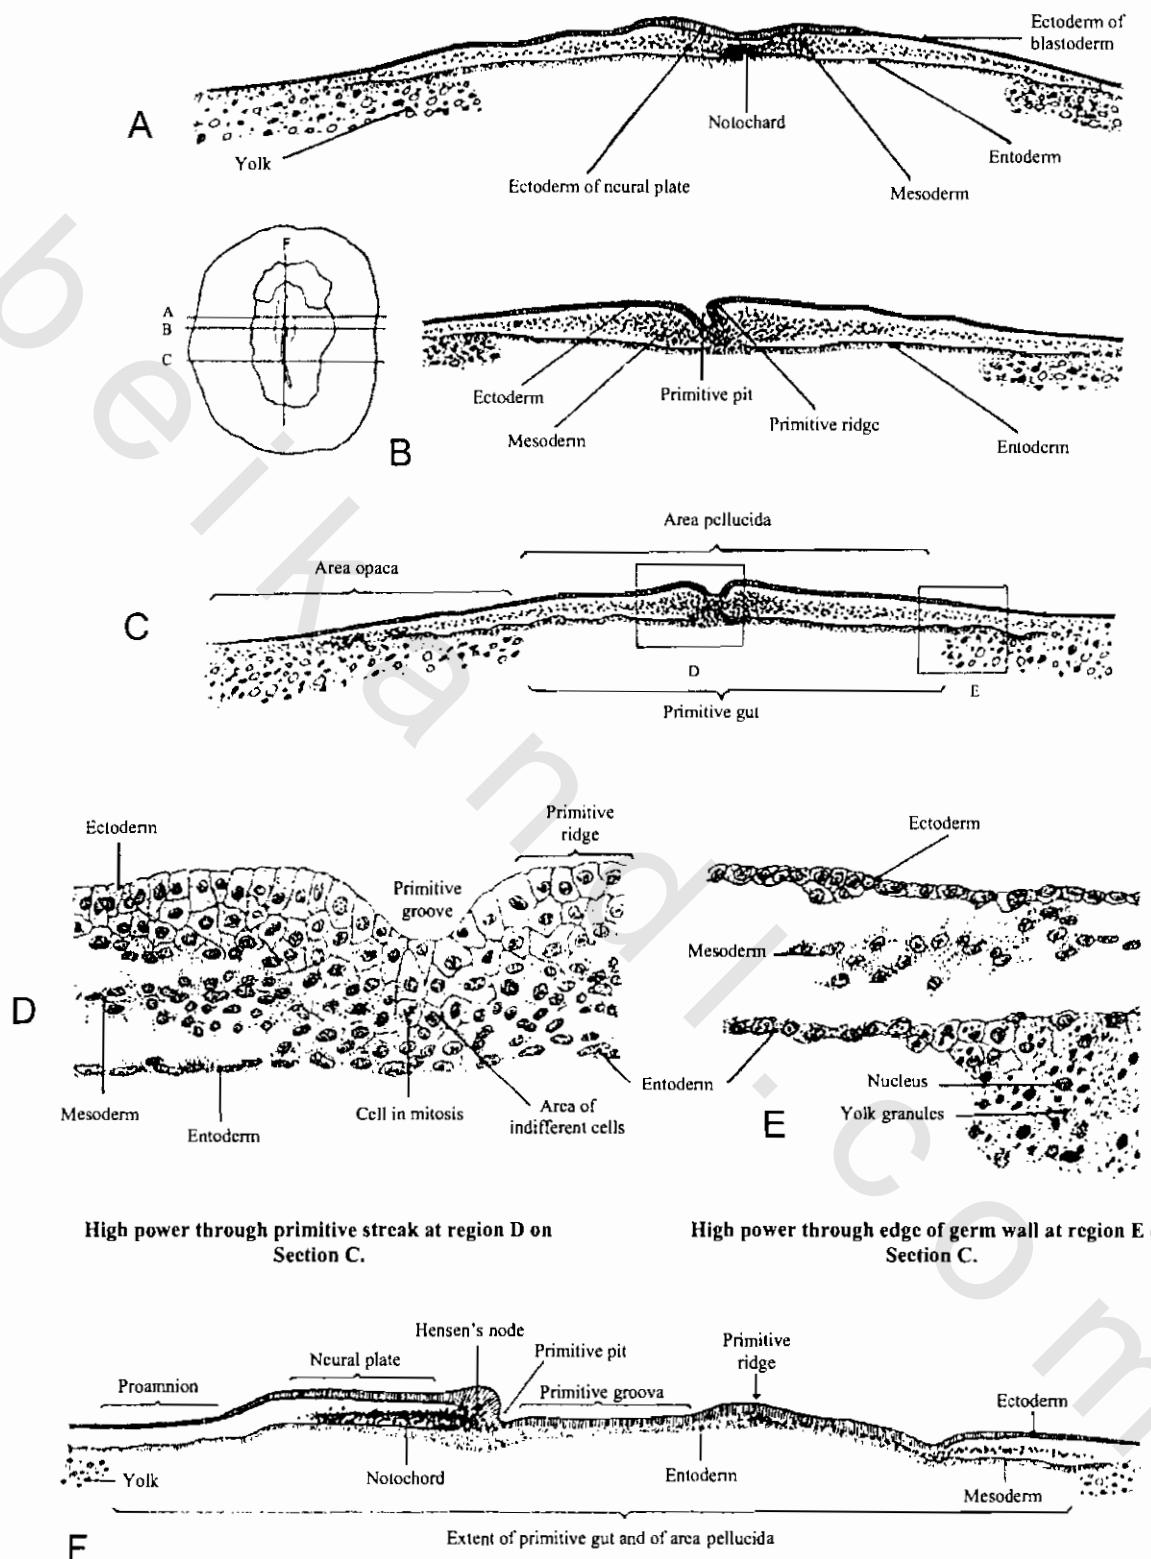

Schematic diagrams indicating the cell movements involved in the gastrulation of chick embryos. (A) Longitudinal section of the blastoderm from a pre-primitive-streak chick during entoderm formation. (B) Longitudinal plan of embryo of approximately 17 hours of incubation to show the relations of the growing notochord, Hensen's node, and the primitive pit. (C) Cross section of embryo in the primitive-streak stage to show the turning in of cells at the primitive groove to enter the mesodermal layers.

تكوين القشور القرنية الموجودة على أرجل الطيور

Stages in the formation of a scale in the bird. (A) Placode stage; (B) asymmetrical placode stage; (C) hump stage; (D) definitive scale ridge stage; (E) mature scale.

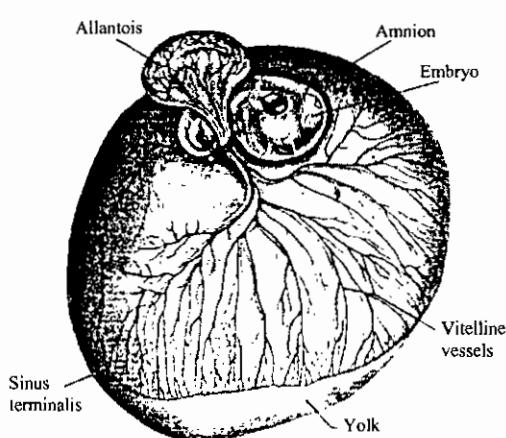

(After Sawyer, 1972, J. Exp. Zool., 181:367.)

منظر جانبی يوضح الدورة الدموية في جنين كتكوت في عمر أربعة أيام

Schematic diagram showing the arrangement of main circulatory channels in a 4-day chick embryo. The sites of some of the extraembryonic interchanges important in its physiology are indicated by the labeling. The vessels within the embryo carry food and oxygen to all its growing tissues, and relieve them of the waste products incident to their metabolism. Abbreviations: AOM, omphalomesenteric (vitelline) artery; VOM, omphalomesenteric (vitelline) vein. [From B. M. Patten, The first heart beats and the beginning of embryonic circulation. American Scientist 39:225 (1951). Used with permission of American Scientist.]

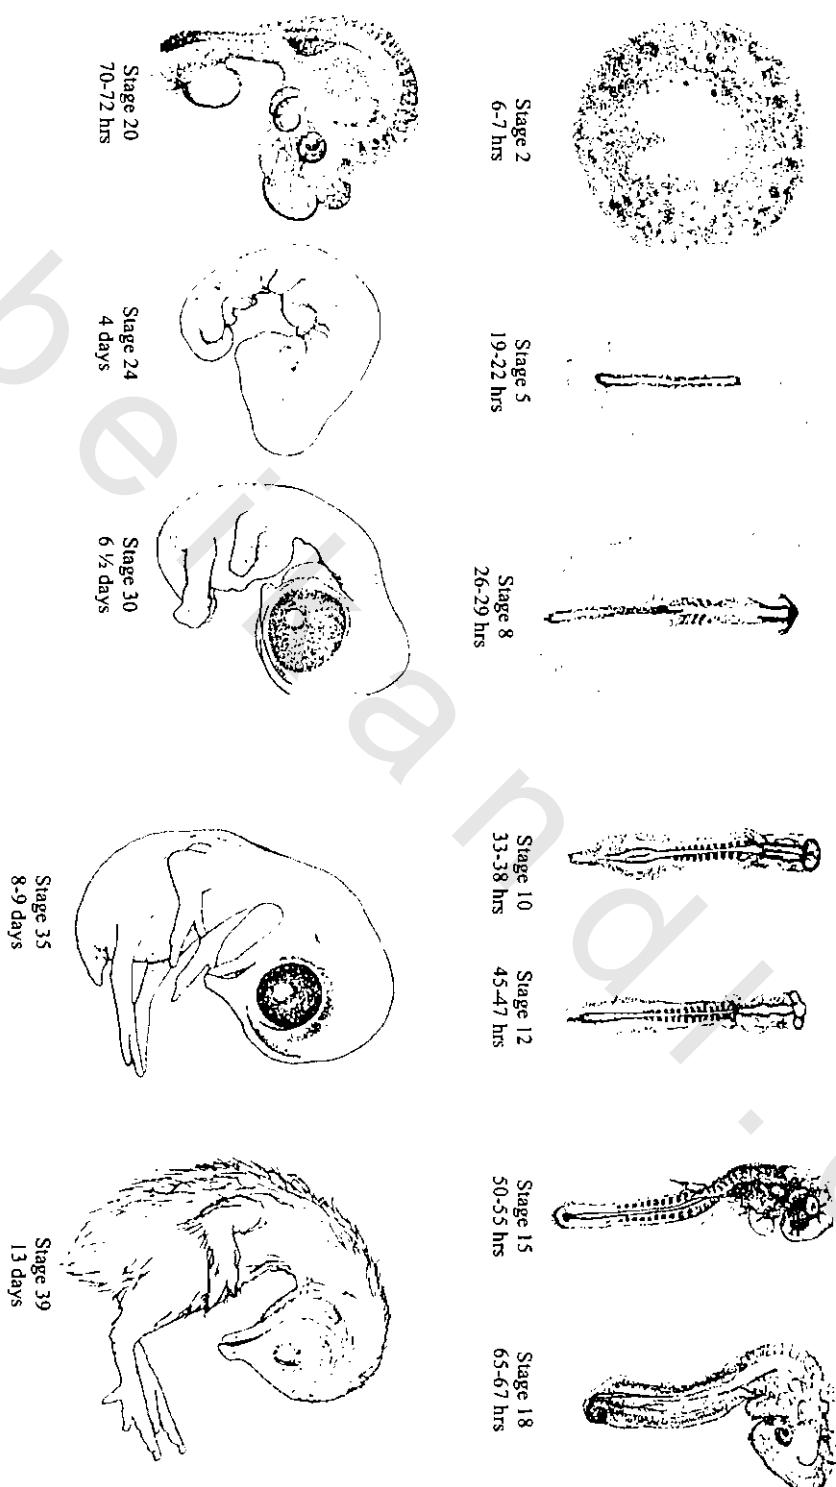

منظر سطحي لجنين كتكوت في عمر خمسة أيام ونصف يظهر الأغشية الجنينية

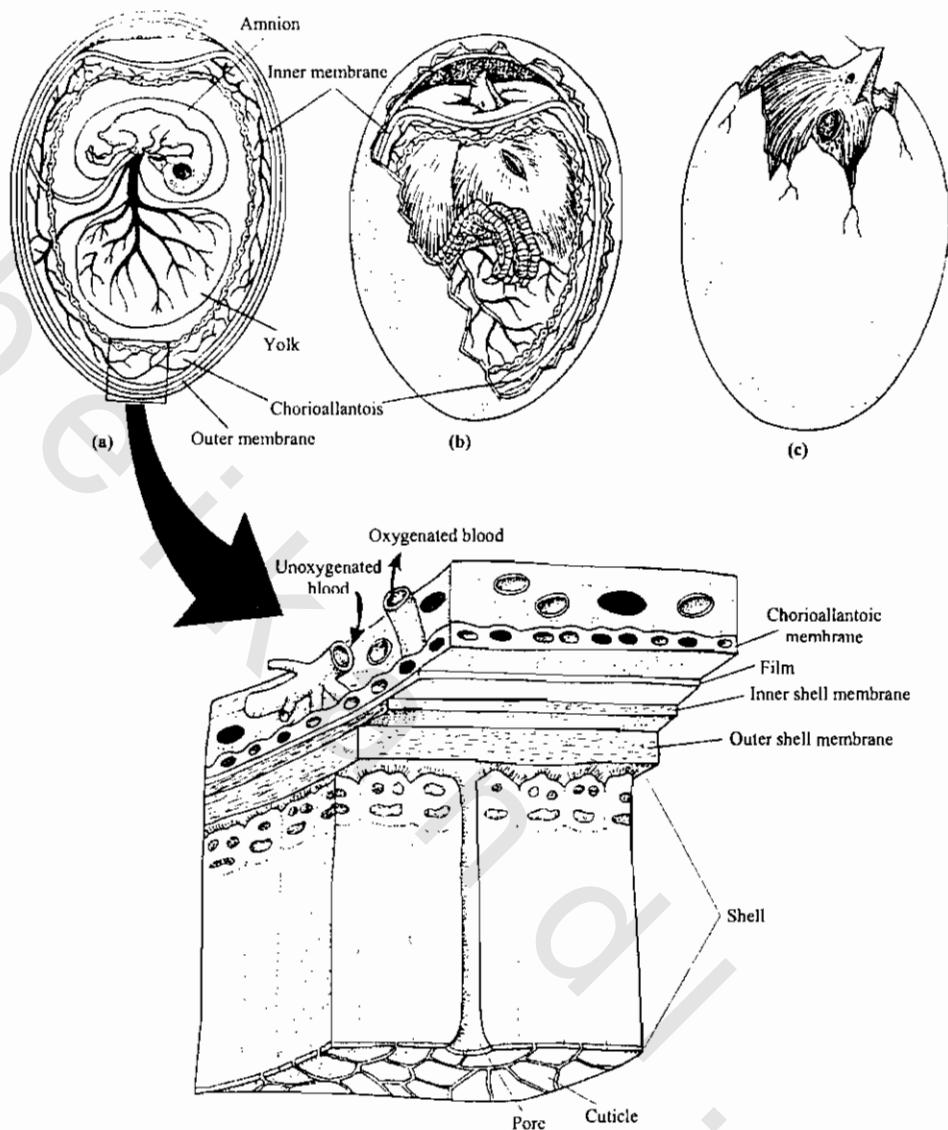

Chick of about 5 1/2 days' incubation taken out of the shell with yolk intact. (Modified from Kerr.) The albumen and the serosa have been removed to expose the embryo lying within the amnion. The allantois has been displaced upward in order to show the relations of the allantoic stalk. Compare this figure with figure 11-1, C, which shows schematically the relations of the membranes in a section through an embryo of similar age.

مراحل في تكوين جنين الكتفوت

Stages in Development of the Chick Embryo (From V. Hamburger and H.L. Hamilton, 1951, J. Morph. 88:49-92.

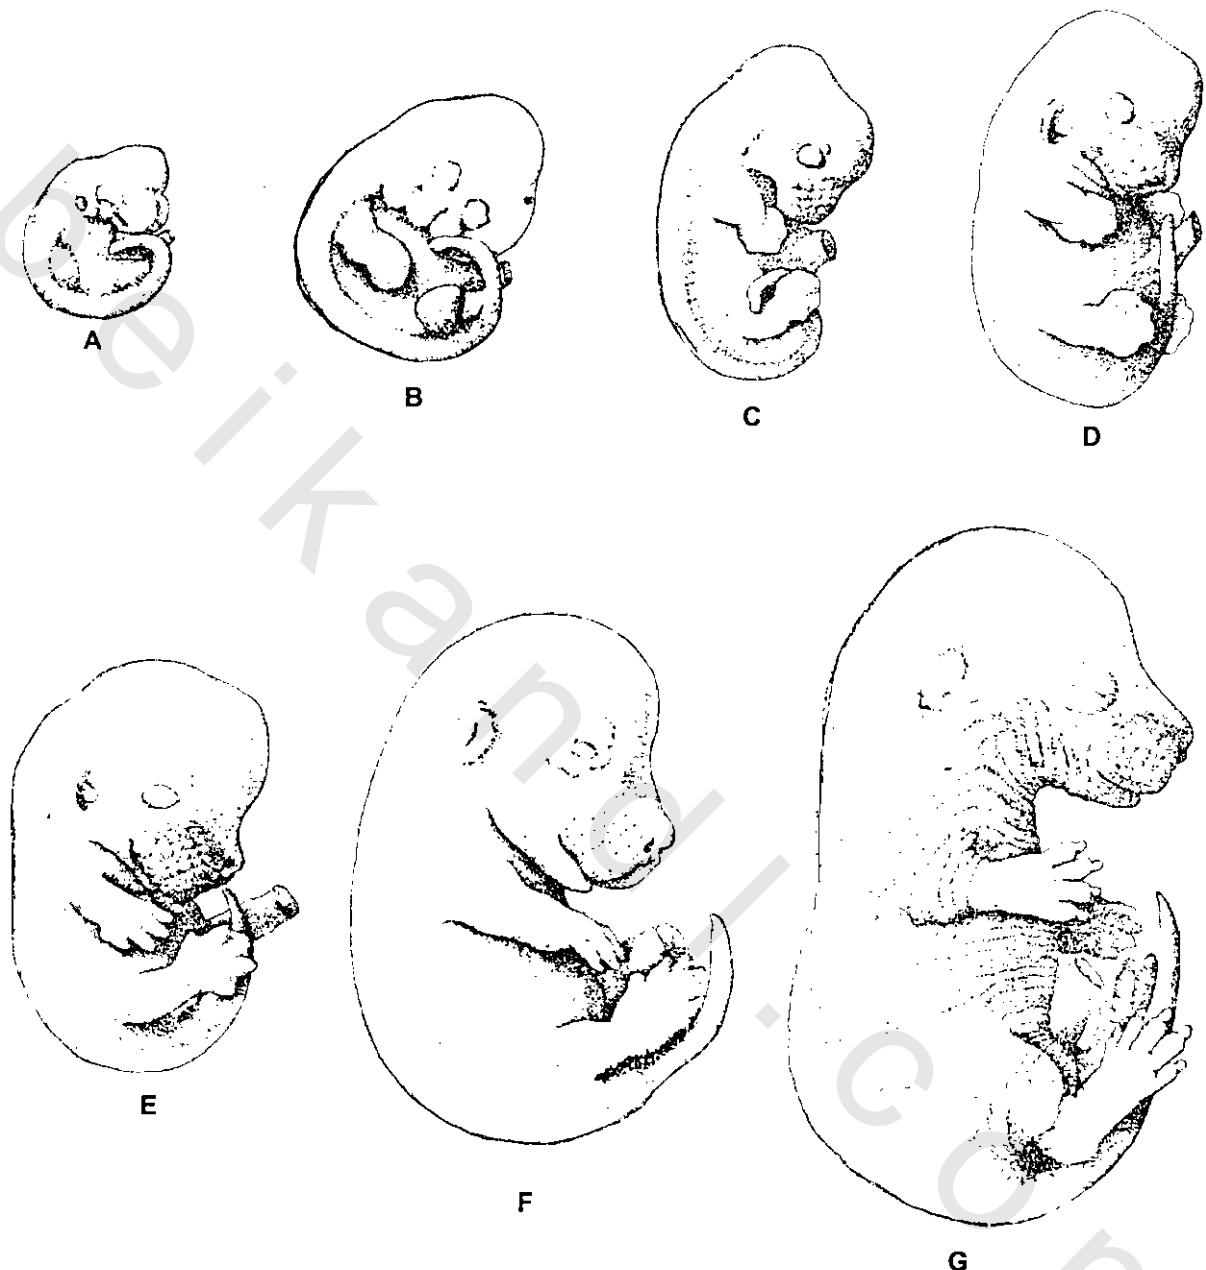

كيفية الفقس في جنين الدجاج والأغشية الخارجية التي يتنفس خلالها

Respiration in the chicken embryo. (a) While the chick embryo is enclosed in its shell, it respires through this porous shell. The chorioallantois carries blood to the inner surface of the shell to exchange gases at this interface. The shell proper is made up of calcite crystals pierced by tiny pores. Inner and outer shell membranes separate the shell from the vascularized chorioallantois. The chick embryo meets all its respiratory needs, up to day 19 of incubation, as air passes through the porous shell and exchanges gases with blood in the

chorioallantois. (b) On day 19, the embryo pokes its beak through the inner shell membrane into the air space between both membranes. Its lungs inflate, and the chick breathes air in addition to continued respiration via the chorioallantois. (c) Six hours later, the chick pecks through the shell proper, a process termed *pipping*, to breathe atmospheric air directly. Thereafter, chorioallantoic respiration declines and the chick further cracks the shell and soon steps out.

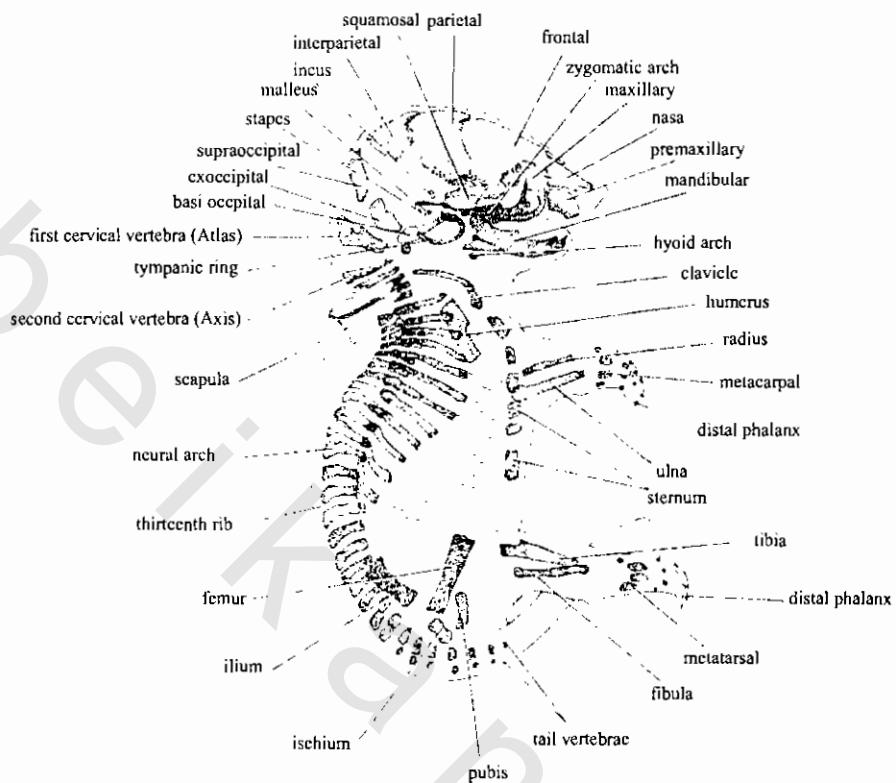

الشكل الخارجى لجنين فأر من عمر عشرة حتى ستة عشر يوما

Mouse embryo, 10 days, L.S. mag. 12X

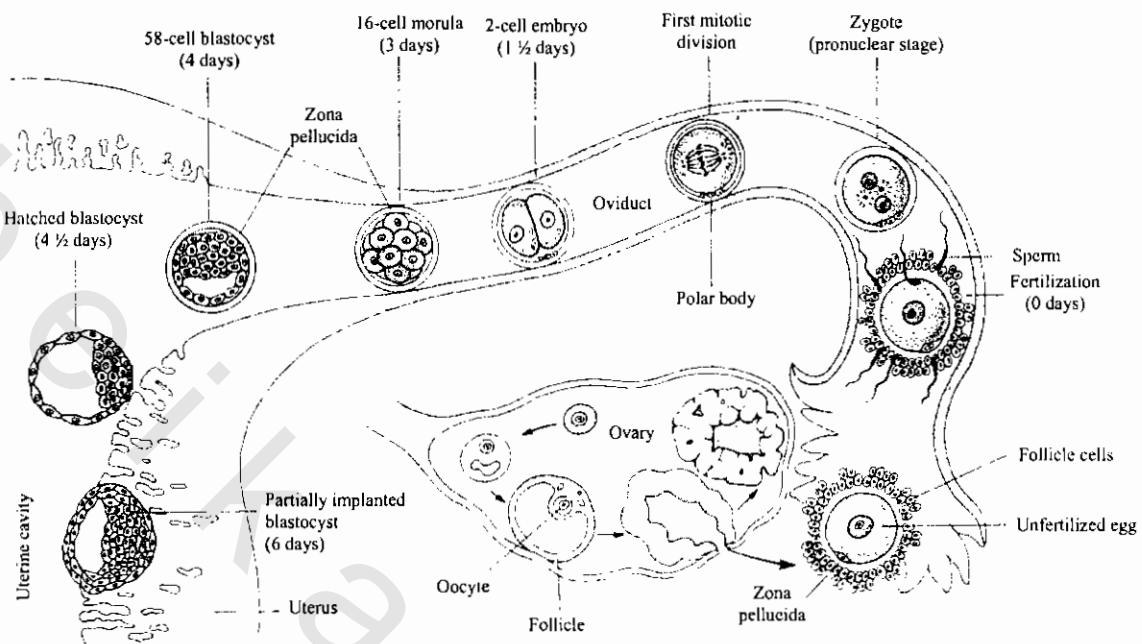

ق. ع. في جنين حيوان ثديي

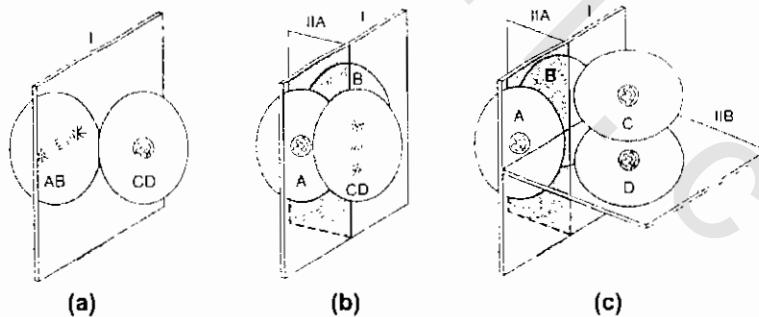

T. s. of a mammalian embryo

Ovulation and the transport of embryo to uterus

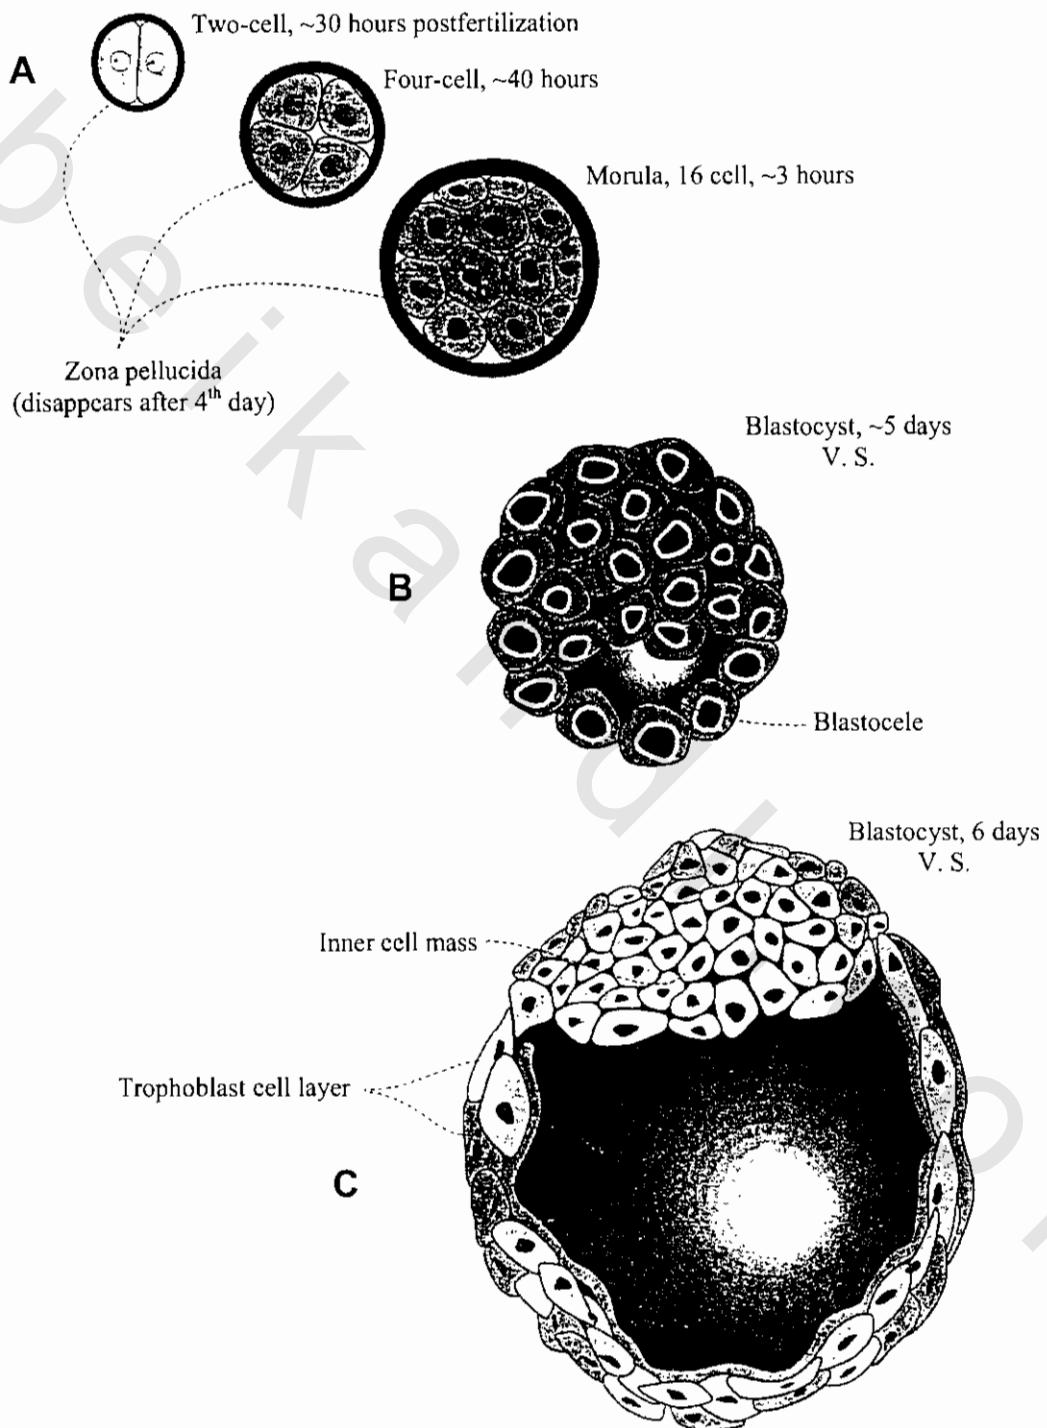

First week of human development. Fertilization occurs in the upper third of the oviduct. The zygote undergoes cleavage as it travels down the oviduct. About 4.5 days after fertilization, the embryo hatches from the zona pellucida and becomes implanted in the inner layer of the uterus.

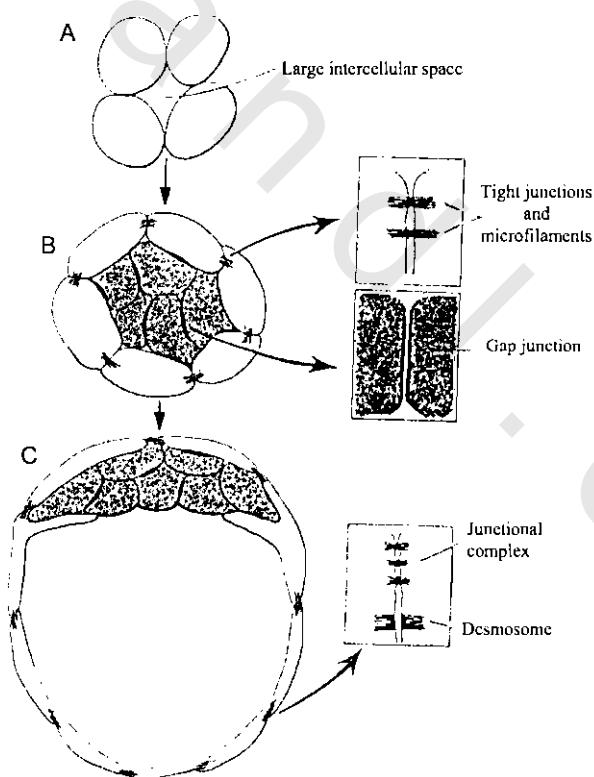

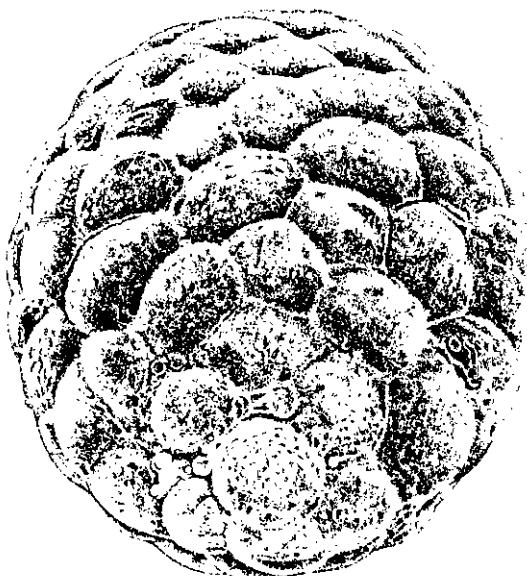

Rotational cleavage in mammals. **(a)** The first cleavage is on a meridional cleavage plane (I) passing through the animal-vegetal axis. The resulting two blastomeres are designated AB and CD. **(b)** The AB blastomere divides first, again on a meridional cleavage plane (IIA). The CD blastomere, which lags behind, elongates parallel to the furrow between A and B. Its mitotic spindle is oriented parallel to the long axis of the cell. **(c)** The CD blastomere divides on a cleavage plane (IIB) that is perpendicular to both I and IIA.

النفج في جنين الإنسان

Cleavage in human embryo

A scanning electron micrograph of a mouse blastocyst. The closely compacted appearance of the cells is attributable to the tight junctions that have developed between them. X 800.

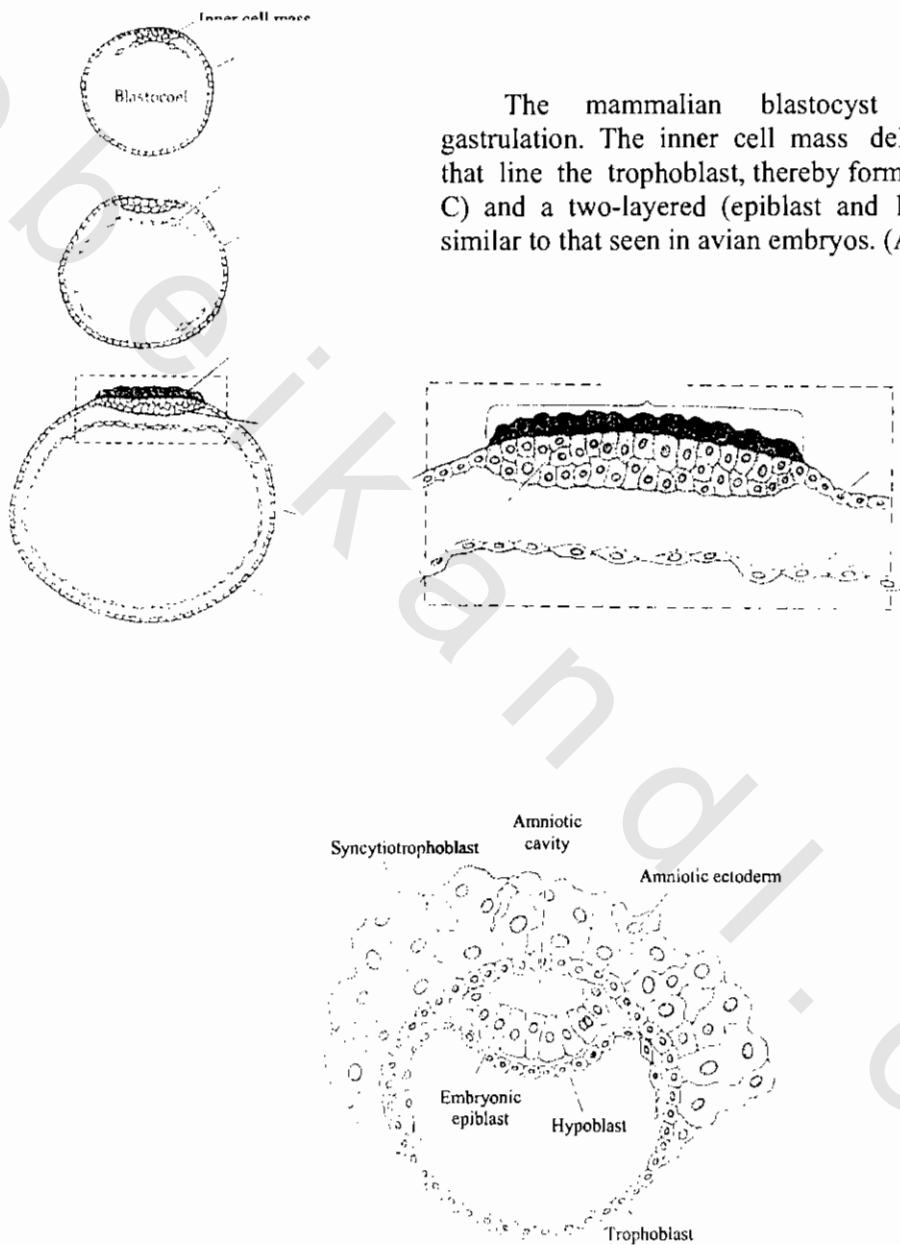

التحام الخلية أثناء التفليج في جنين الفأر

Cell junctions during cleavage of the mouse embryo. (Adapted from Denker, 1983.)

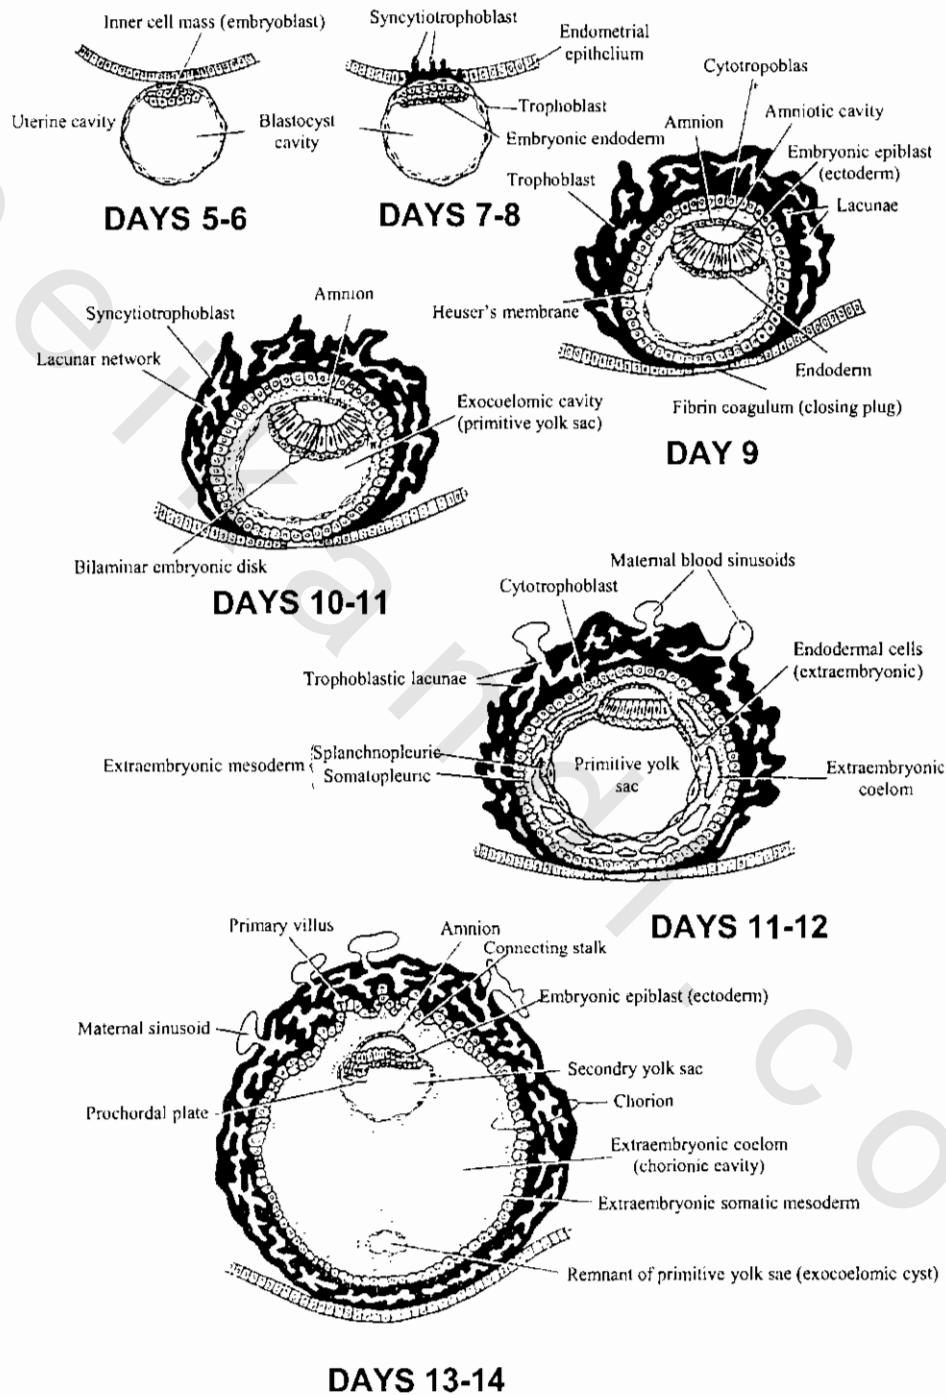

تكوين القرص الجنيني ذو الطبقتين في جنين الإنسان

Formation of two-layered blastodisc in human embryo

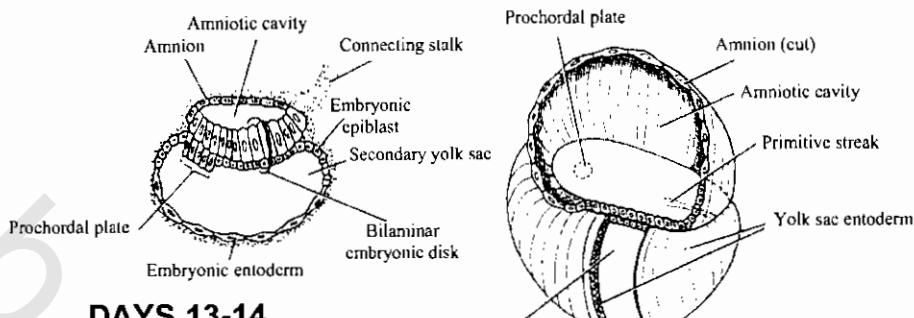

Formation of the amnion in human embryos. The hypoblast is complete near the site of the inner cell mass, and the trophoblast cells are dividing to form the syncytiotrophoblast, which will invade the uterus. Meanwhile, the epiblast has split into the amniotic ectoderm and the embryonic epiblast. All subsequent development of the embryo will focus on the embryonic epiblast. (After Carlson, 1981.)

Schematic drawing of placental structure. Arrows indicate the blood flow from decidual arteries to intervillous space and back to decidual veins. This direction is determined by the difference in pressure between arterial and venous blood. (Redrawn and reproduced, with permission, from Duplessis GDT, Haegel P: *Embryologie*. Masson, 1971. [English edition © Springer-Verlag, 1972; Masson, 1972.])

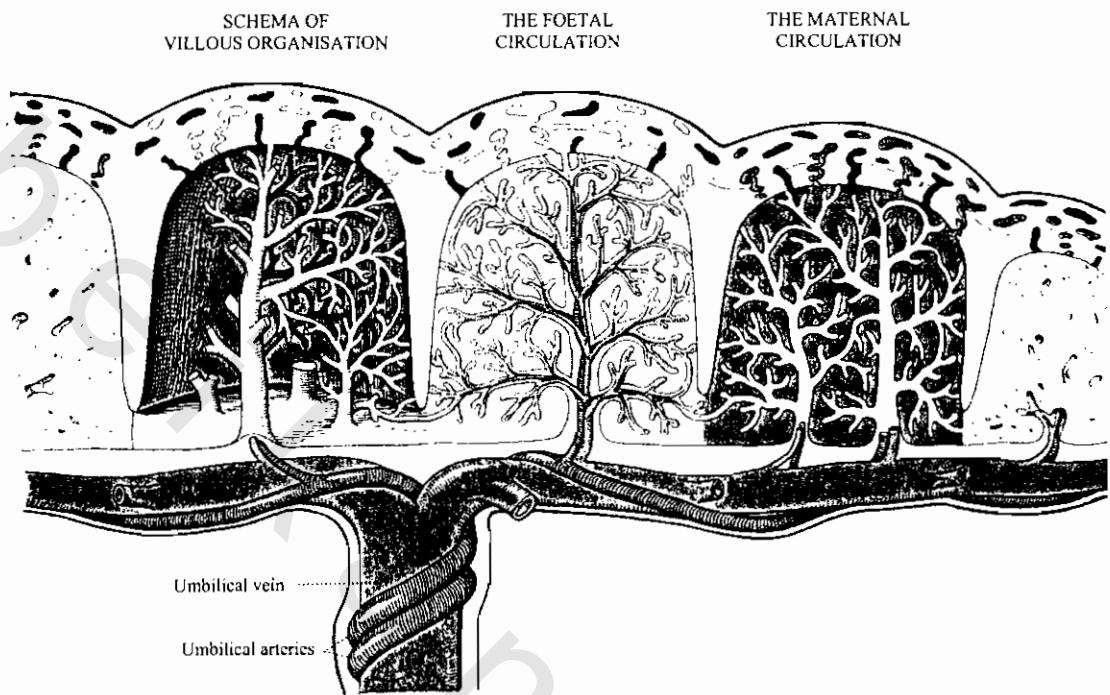

تكوين الحبل السري في جنين الإنسان
Development of human umbilical cord

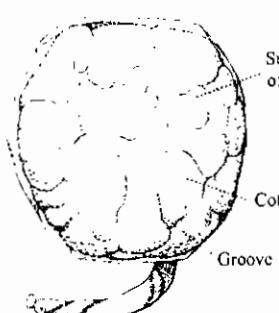

Embryo and membranes of a placental mammal, showing placental development from fused chorion and allantoic wall, extending as fingerlike villi that interlock with uterine tissue.

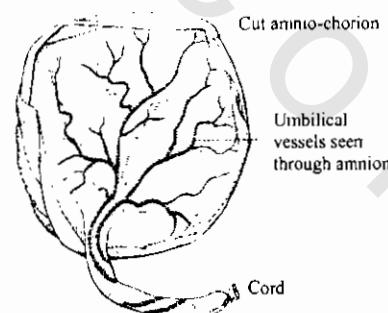

A, Schematic drawing of a 5-week embryo to show the structures passing through the primitive umbilical ring. **B**, Schematic drawing of the primitive umbilical cord of a 10-week embryo. **C**, Transverse section through the structures at the level of the umbilical ring. **D**, Transverse section through the primitive umbilical cord, showing the intestinal loops protruding in the cord.

FOETAL SURFACE

MATERNAL SURFACE

مقارنة بين الأغشية الجنينية للدجاج والخنزير والإنسان

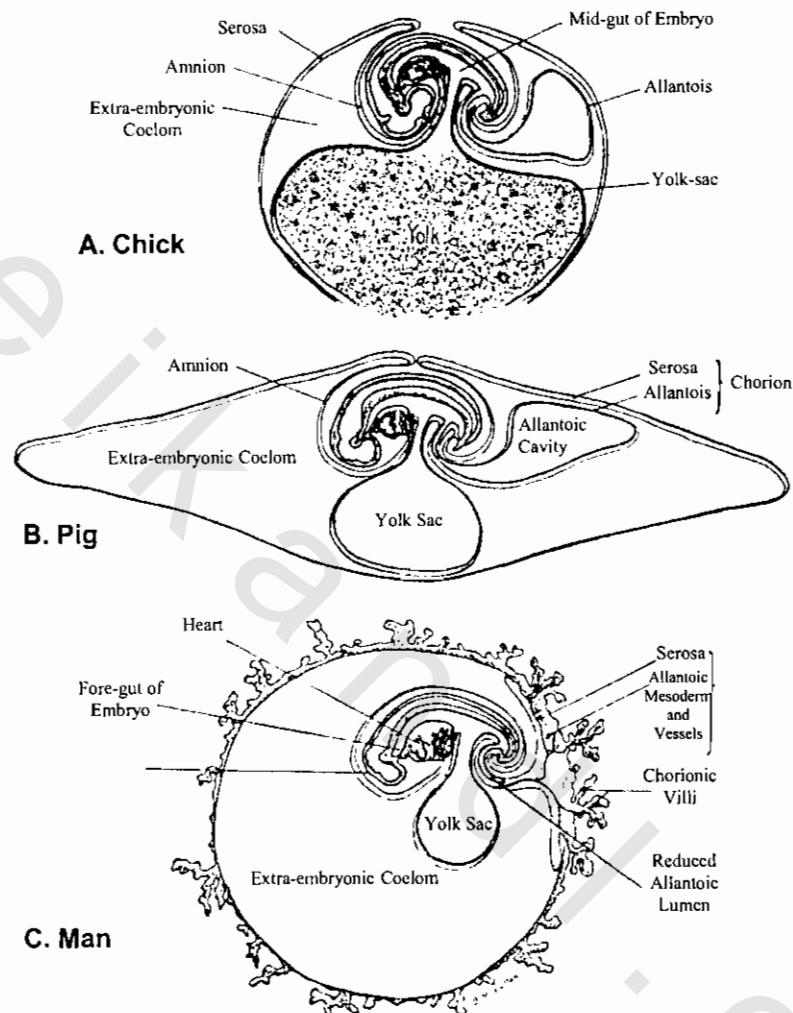

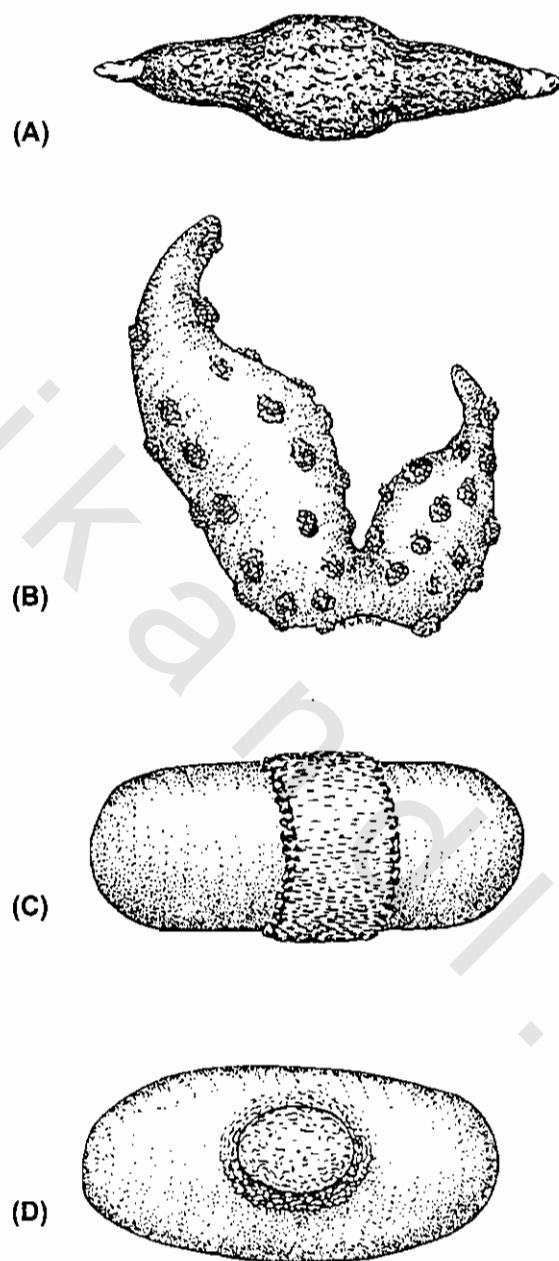

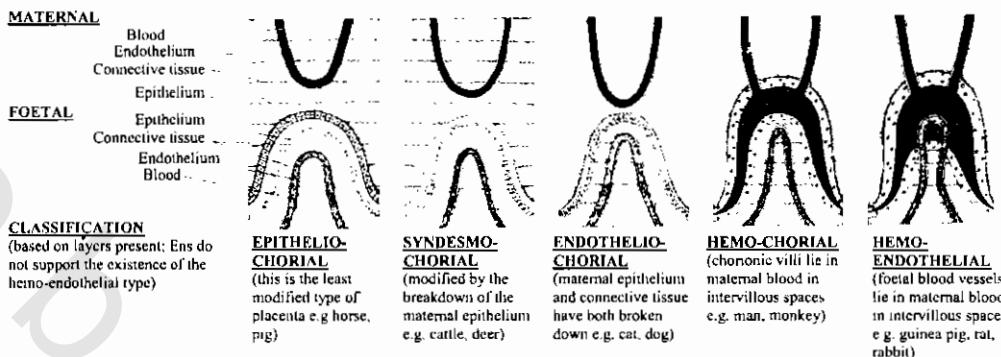

Diagram showing interrelations of embryo and extra-embryonic membranes characteristic of higher vertebrates. Neither the absence of yolk from its yolk-sac nor the reduction of its allantoic lumen radically changes the human embryo's basic architectural scheme from that of more primitive types.

أنواع الأكياس السلوية في الثدييات حسب توزيع الخملات على سطحها

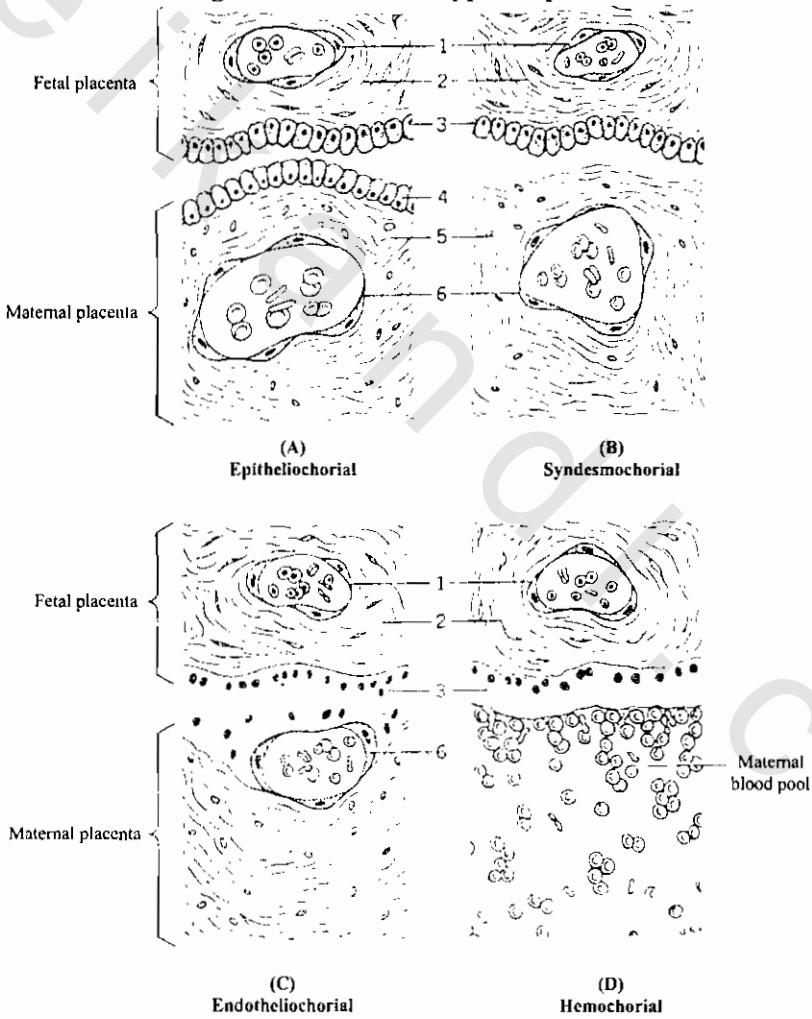

Diagrams of chorionic sacs of representative mammals, showing gross forms of the placenta. (A) Diffuse placenta of the big. (B) Cotyledonary placenta of the sheep. (C) Zonary placenta of the dog. (D) Discoidal placenta of the bear.

الأنواع النسيجية في مشيمة الثدييات المختلفة

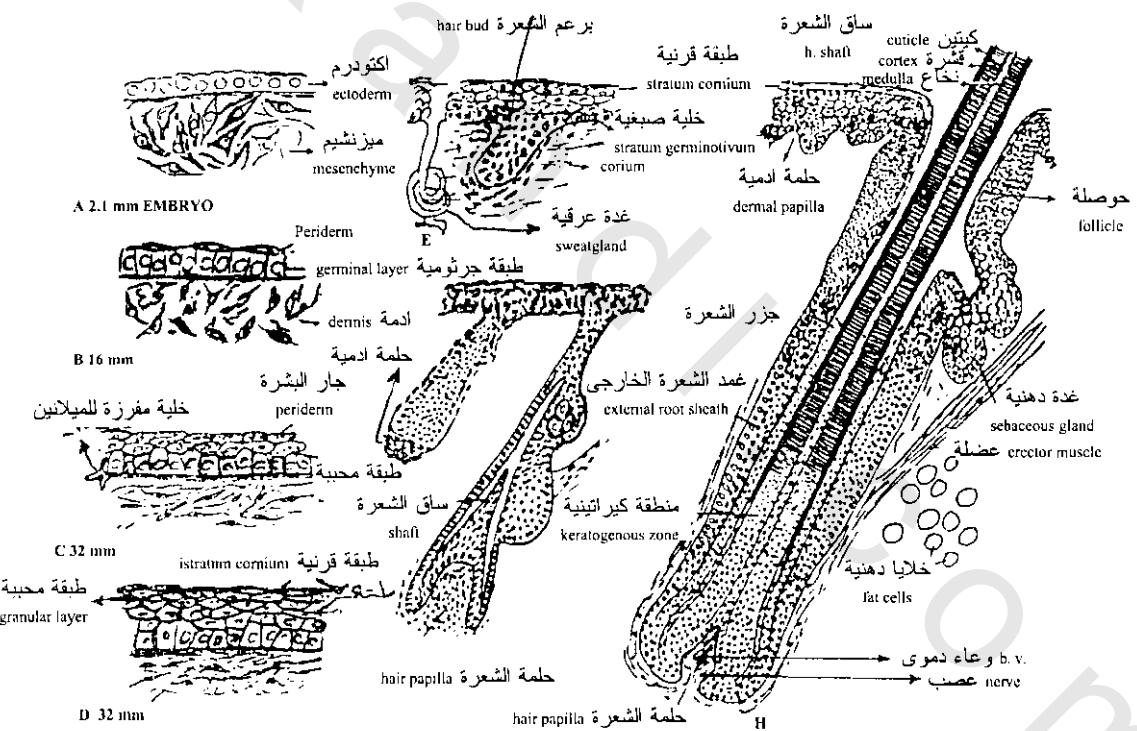

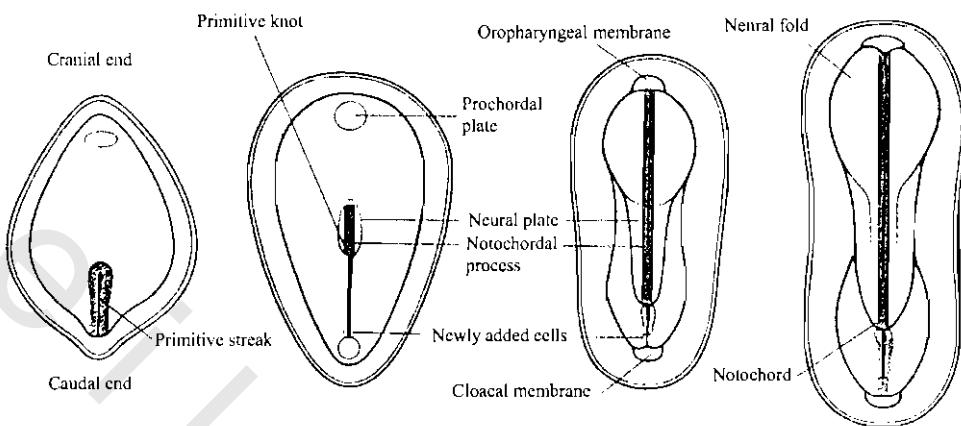

Diagrams of different types of placenta

Histological types of mammalian placentae. 1- endothelium of fetal blood vessel. 2- chorionic connective tissue. 3- chorionic epithelium. 4- uterine epithelium. 5- endometrial connective tissue (mucosa). 6- endothelium of maternal blood vessel.

تكوين الشق البدائي وعقدة هنسن في جنين الانسان

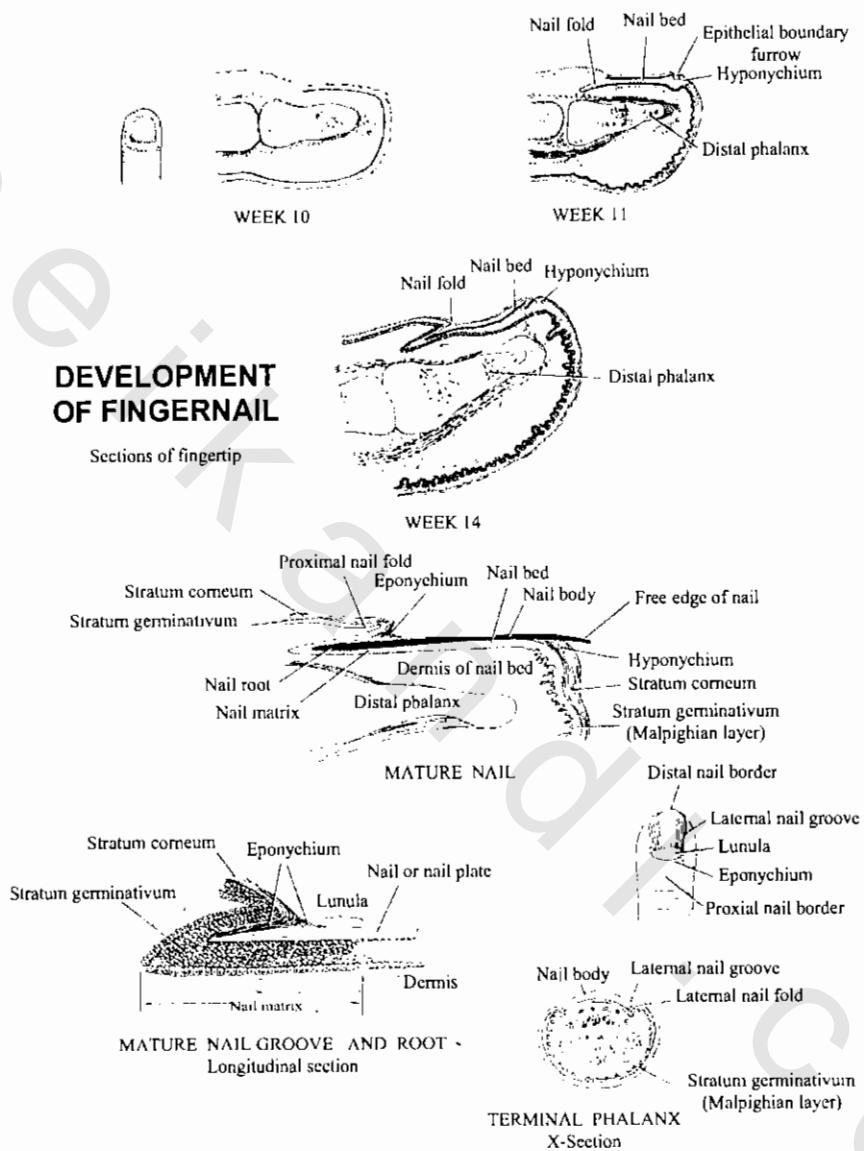

The appearance of the primitive streak and primitive knot along the embryonic disc. These progressive changes occur through the process of induction.

مراحل تكوين الجلد والشعر في الثدييات

Development of the human epidermis and hair follicle. A, epidermis of 2.1 mm embryo / B, epidermis of 16-mm embryo: C, epidermis of 32-mm embryo: D, epidermis of 85-mm embryo / E to H, progressive stages in the development of the follicle and hair. (After Potten, 1946).

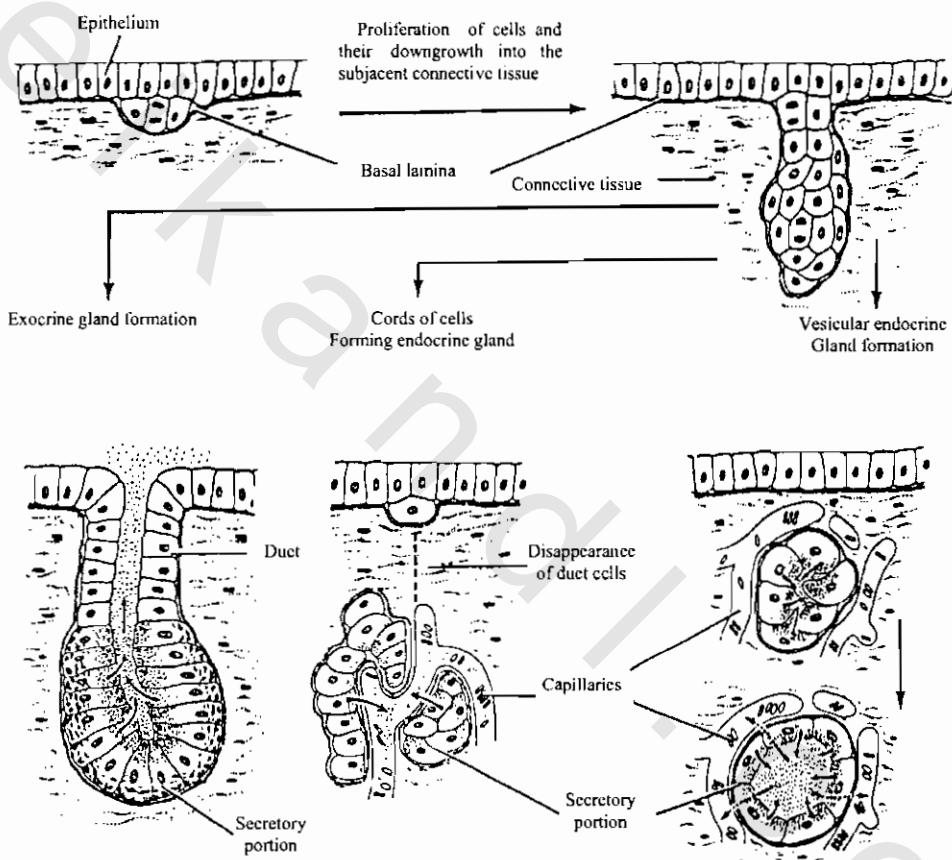

تكوين الظفر في الإصبع

Development of glands:

Glands are formed in the following sequence

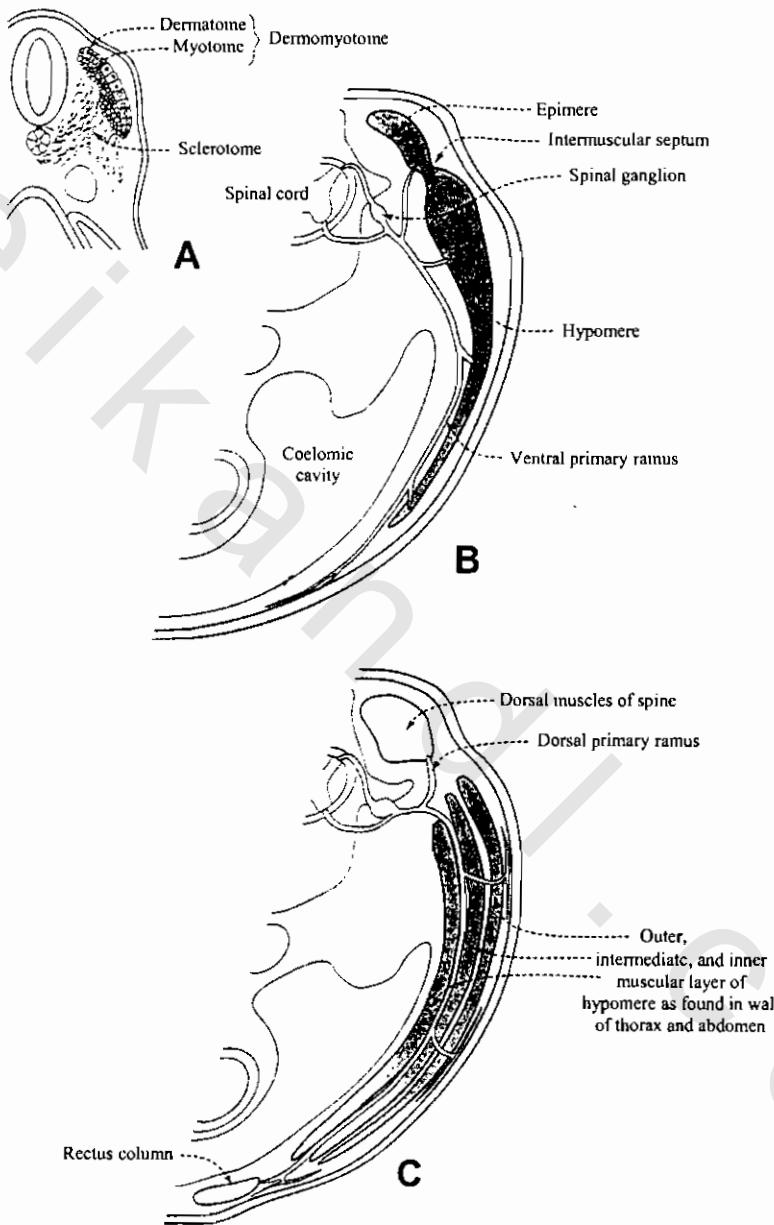

- 1- Invagination of a solid cord of epithelial cells.
- 2- Branching of the cord.
- 3- Cords hollow out to produce ducts.
- 4- Ends of branches hollow out to produce acini.

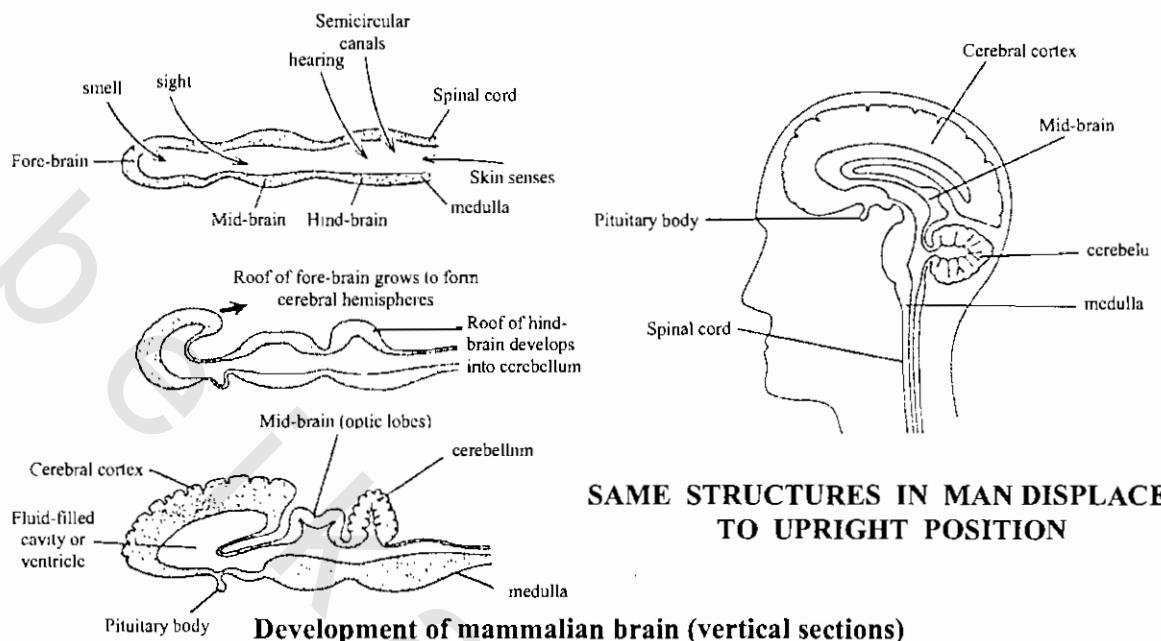

Formation of glands from covering epithelia. Epithelia cells proliferate and penetrate into connective tissue. They may or may not maintain contact with the surface. When contact is maintained, exocrine glands are formed; when contact is not maintained, endocrine glands are formed. The cells of these glands can be arranged in cords or follicles. The lumens of follicles accumulate large quantities of secretion; cells of the cords store only small quantities in their cytoplasm. (Redrawn and reproduced, with permission, from Ham AW: *Histology*, 6th ed. Lippincott, 1969.)

قطاعات ع. في أجنة الإنسان توضح تميز القطعة الميوزودرمية ثم تميز العضلات المختلفة وإمدادها بالأعصاب

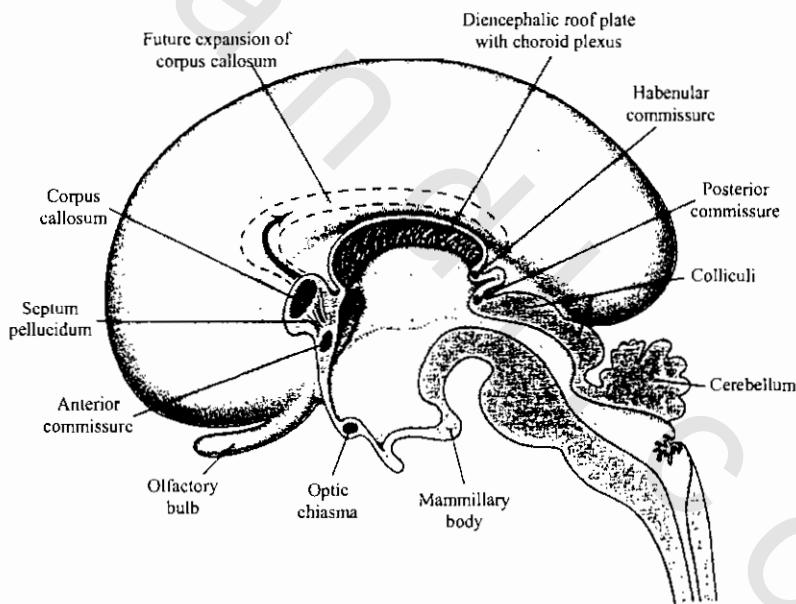

T. s. of human embryos showing differentiation of the mesodermal somites and the differentiation of the muscles and their innervation

SAME STRUCTURES IN MAN DISPLACED TO UPRIGHT POSITION

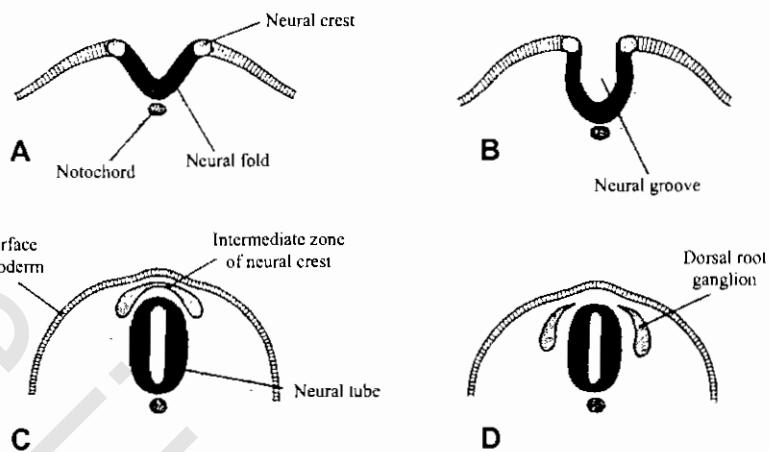

Development of mammalian brain (vertical sections)

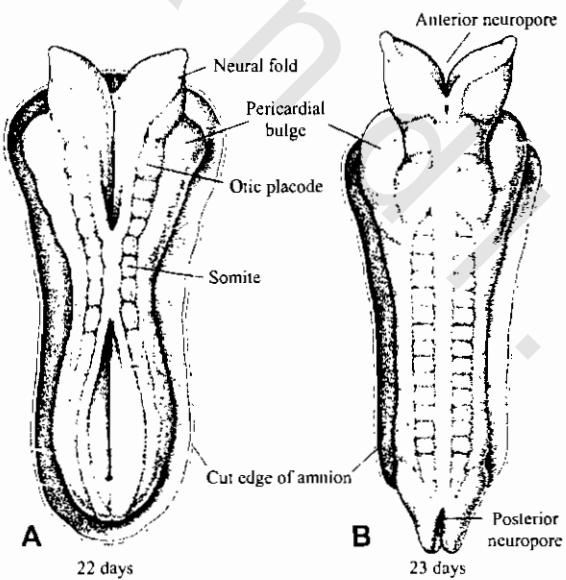

تركيب مخ الإنسان

L. View of the medial surface of the right half of the brain in a 4-month embryo, showing the various commissures. The broken line indicates the future expansion of the corpus callosum. The hippocampal commissure is not indicated.

تكوين الأنوية العصبية في جنين الإنسان

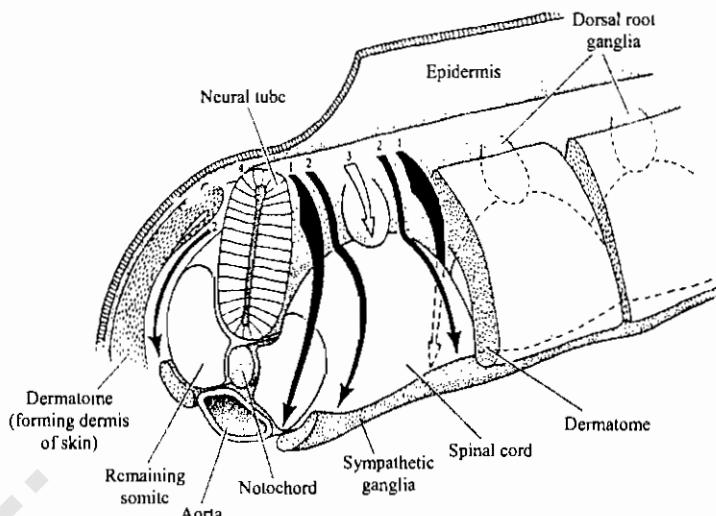

Schematic drawings of a number of transverse sections through successively older embryos, showing the formation of the neural folds, neural groove, and neural tube. The cells of the neural crest, initially forming an intermediate zone between the neural tube and surface ectoderm (**C**) develop into the dorsal root and cranial sensory ganglia (**D**).

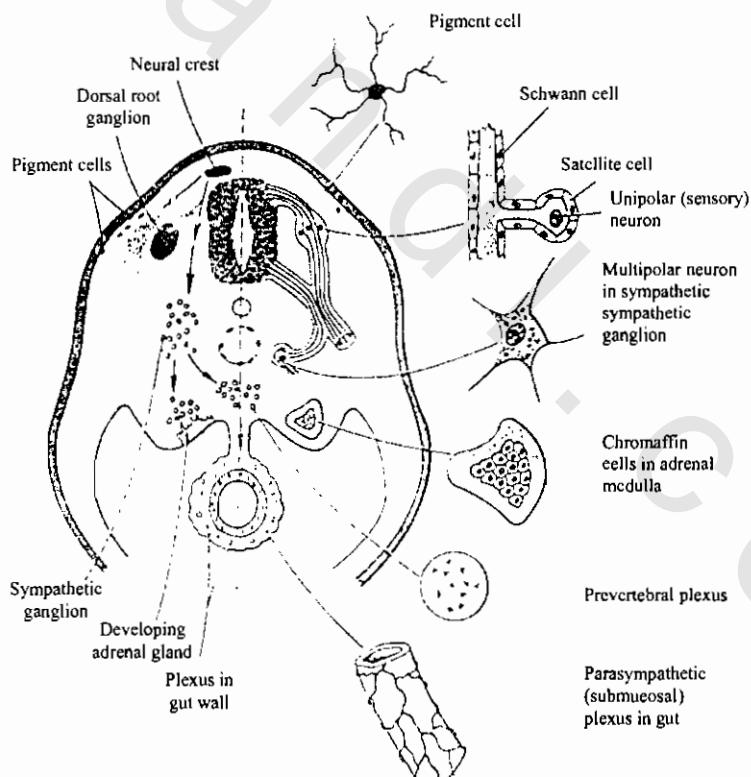

A, Dorsal view of a human embryo at approximately day 22. (Modified after Payne.) Seven distinct somites are visible on each side of the neural tube. **B**, Dorsal view of a human embryo at approximately day 23. (Modified after Corner.) Note the pericardial bulge on each side of the midline in the cephalic part of the embryo.

هجرة خلايا العرف العصبي وتمييزها في الأعضاء المتكونة منها

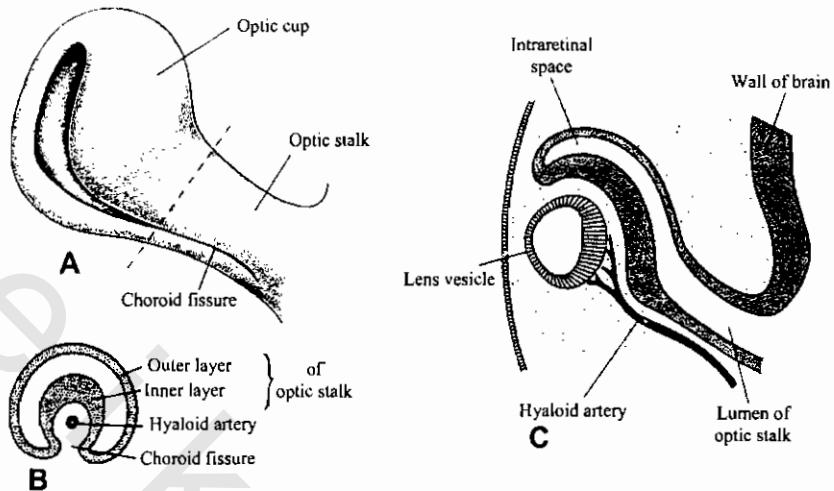

Paths of neural crest cell migration in the trunk of an embryo. Path 1 between adjacent somites, results in the formation of the sympathetic ganglia and adrenal medullary cells. In other regions of the trunk, neural crest cells form the parasympathetic ganglia. Those cells taking path 2 also contribute to the sympathetic ganglia. Neural crest cells migrating in path 3 become the neurons of the dorsal root ganglia, and those neural crest cells migrating beneath the ectoderm (4) give rise to the pigment cells.

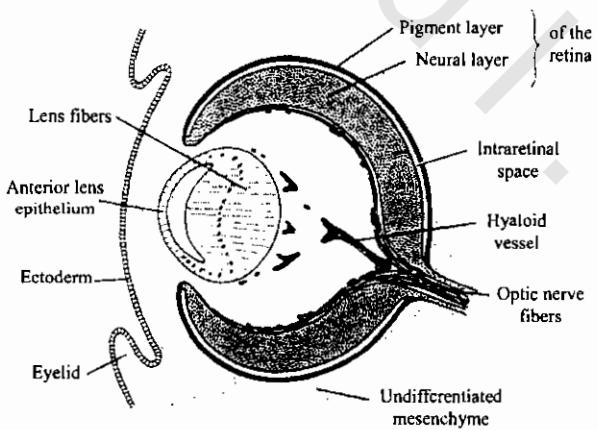

Major neural crest migratory pathways and derivatives in the trunk. Left: Pathways in the early embryo. Right: Derivatives of the trunk neural crest.

تكوين العين في الإنسان

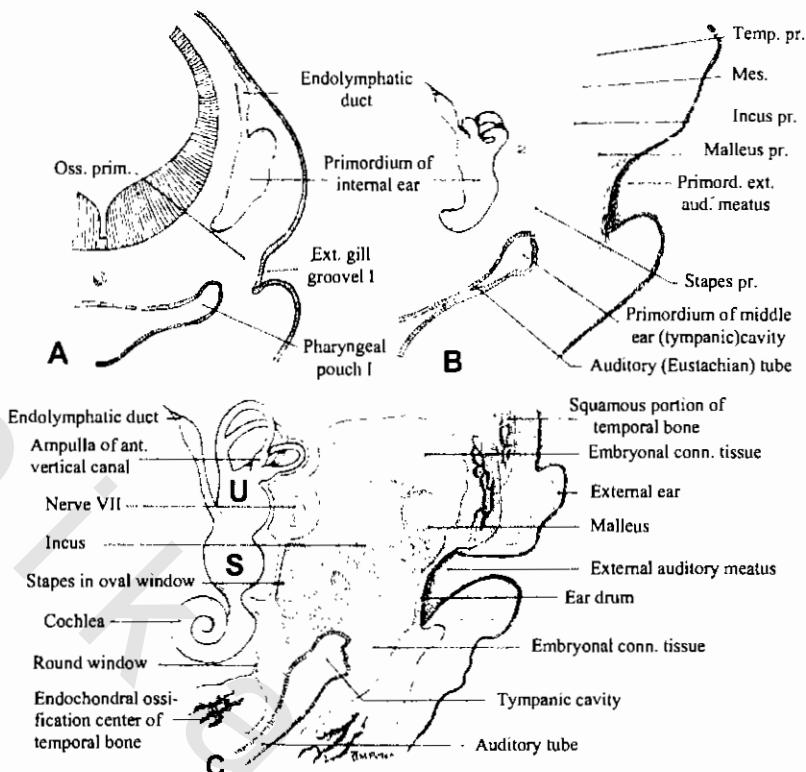

A, Ventrolateral view of the optic cup and optic stalk of a 6-week embryo. The choroid fissure located on the undersurface of the optic stalk gradually tapers off. B, Transverse section through the optic stalk as indicated in A, showing the hyaloid artery in the choroid fissure. C, Section through the lens vesicle, the optic cup, and optic stalk at the plane of the choroid fissure. (After Mann IC: The Development of the Human Eye, ed 3 [British Medical Association]. New York, Grune & Stratton, 1974.)

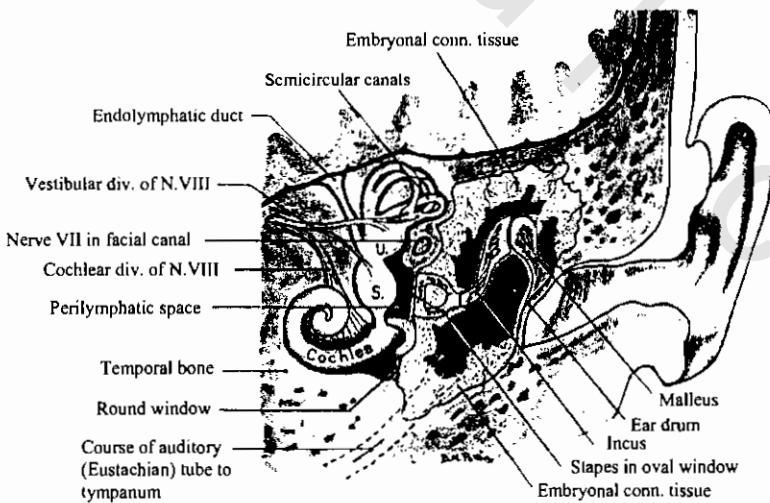

Anteroposterior section through the eye of a 7-week embryo. The eye primordium is completely embedded in mesenchyme. The fibers of the neural retina converge toward the optic nerve. (Modified after Mann IC: The Development of the Human Eye, ed 3 [British Medical Association]. New York, Grune & Stratton, 1974.)

تكوين الأذن في الإنسان

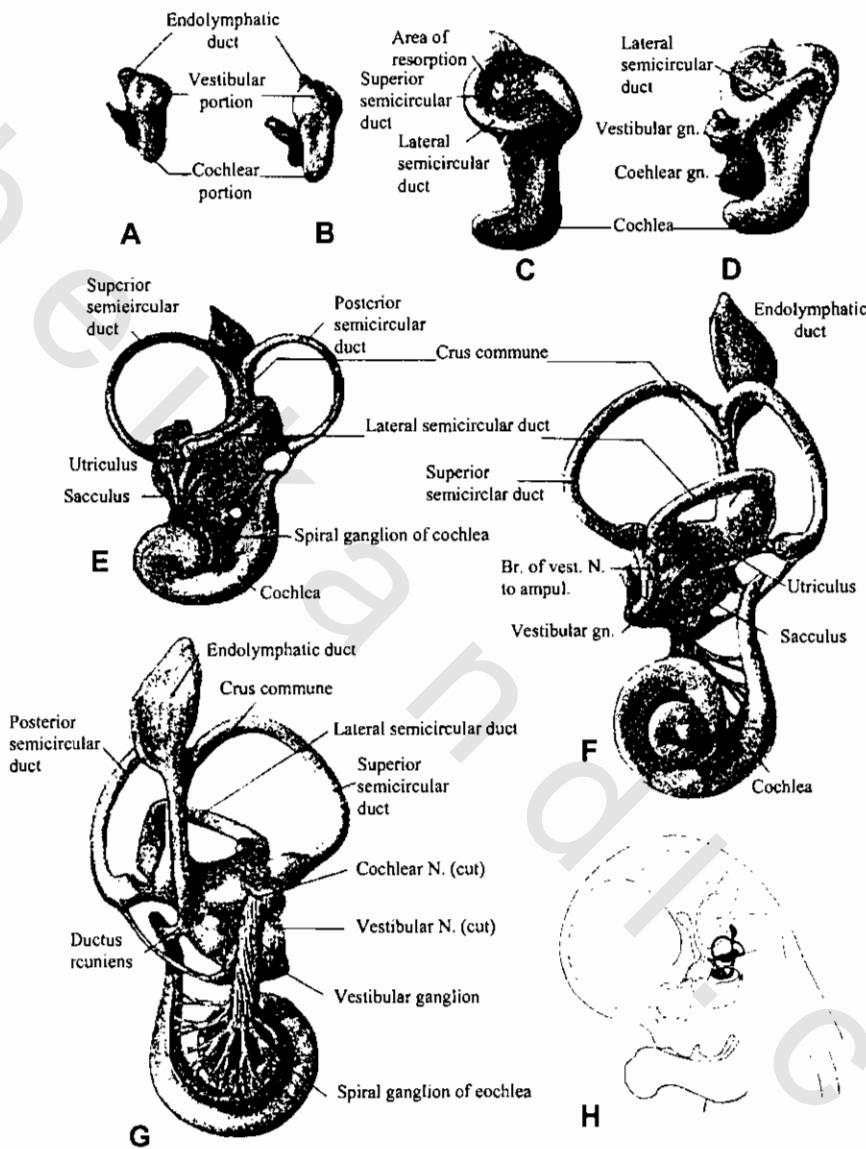

Schematic diagrams showing three stages in the development of the middle-ear chamber and the auditory ossicles. Abbreviations: Mes. -mesenchyme; Oss. Prim.-mesenchymal concentration which is the first indication of the primordia of the auditory ossicles; Temp. pr.-mesenchymal concentration where primordium of temporal bone is taking shape.

Semischematic diagram showing ear mechanism at term. The cochlea has been turned mesiad to show its spiral course.

تكوين التيه السباتي في أذن الإنسان

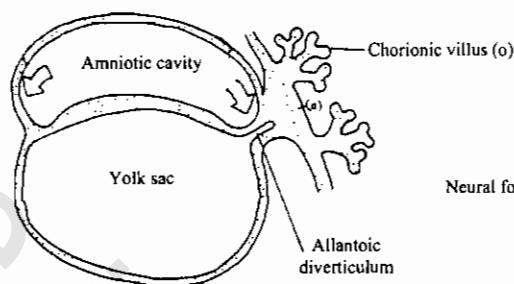

Development of the membranous labyrinth in human embryos. (After Streeter, Am. J. Anat., vol. 6, 1906.) (A) 6 mm, lateral view. (B) 9 mm, lateral view. (C) 11 mm, lateral view. (D) 13 mm, lateral view. (E) 20 mm, lateral (F) 30 mm, lateral view. (G) 30 mm, medial aspect. (H) Outline of head of 30-mm embryo to show position and relations of developing inner ear.

Section of mammalian tooth set in the jaw (after Hom. 1957)

بداية تكوين المعى في جنين الثدييات

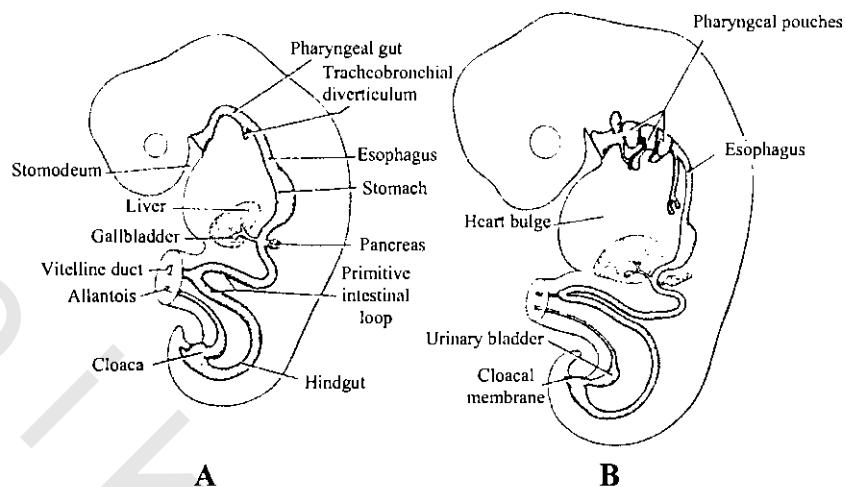

Schematic longitudinal section of an amniote embryo, showing the architecture of the embryonic gut.

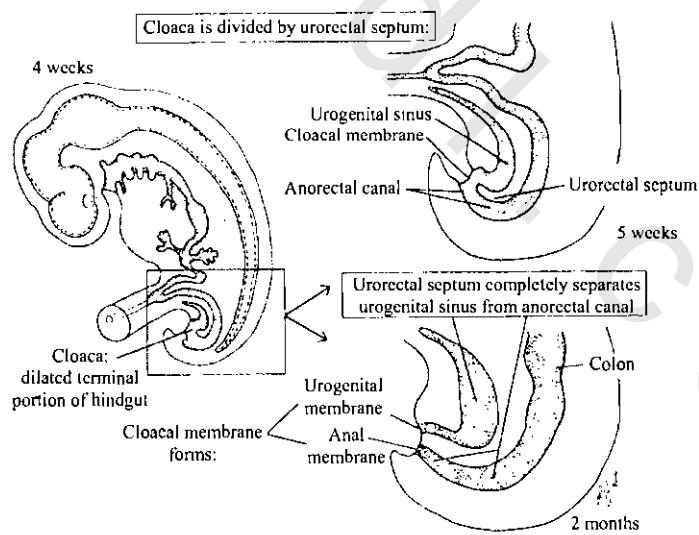

Schematic representation of the subdivisions of the alimentary canal. (All accessory parts and derivatives omitted.)

الأجزاء الأساسية للمعى وتميز المعى الخلفي

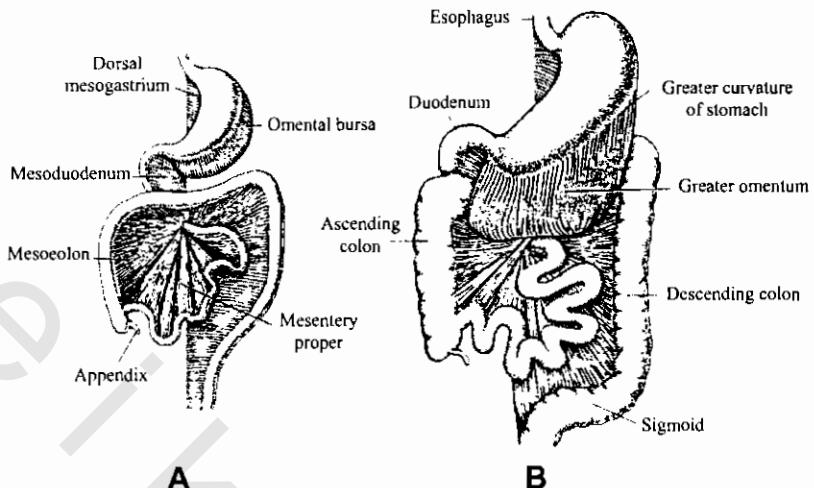

Development of the rectum and anal canal

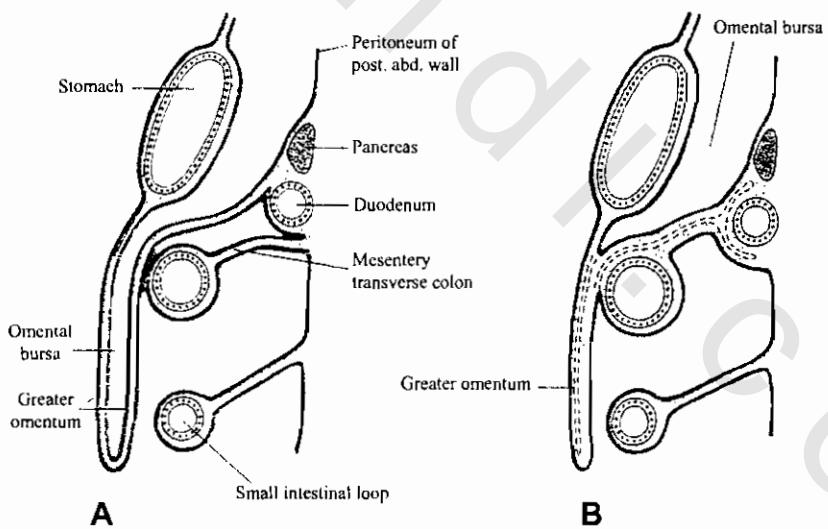

Schematic drawings of embryos during the 4th and 5th weeks of development to show the formation of the gastrointestinal tract and the various derivatives originating from the endodermal germ layer.

تكوين مسارات الأمعاء

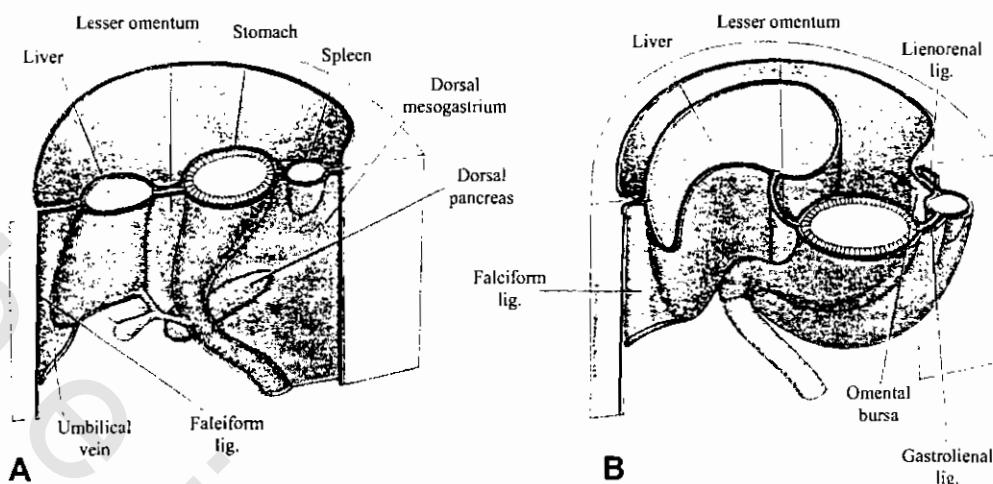

A, Schematic drawing of the dorsal mesentery at the end of the 3rd month. The dorsal mesogastrum bulges out on the left side of the stomach, where it forms the omental bursa. B, The greater omentum hangs down from the greater curvature of the stomach in front of the transverse colon.

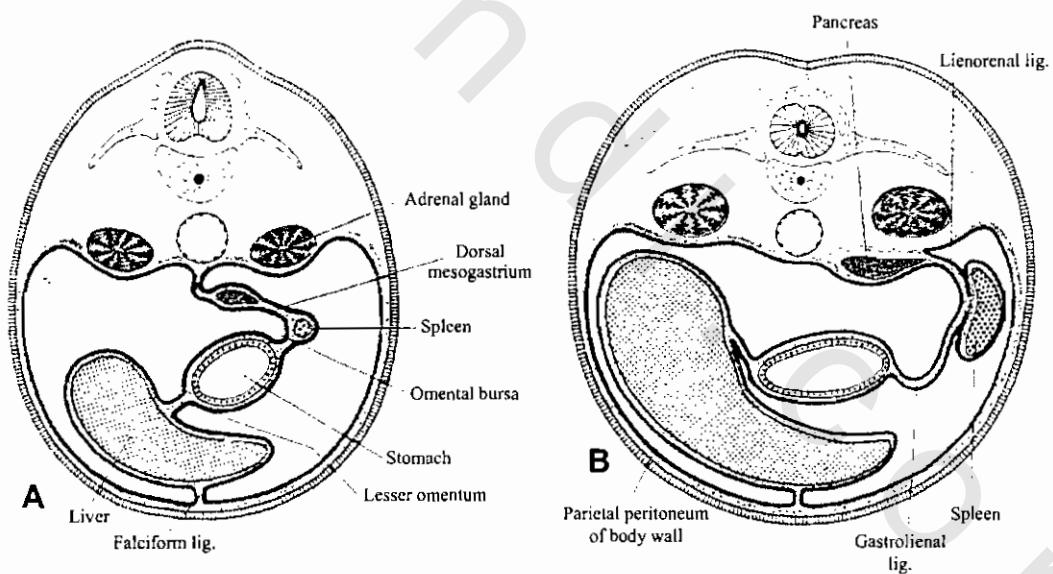

A, Schematic sagittal section showing the relationship between the greater omentum, stomach, transverse colon, and small intestinal loops at 4 months. The pancreas and duodenum have already acquired a retroperitoneal position. B, Similar section as in A, in the newborn. The leaves of the greater omentum have fused with each other and with the transverse mesocolon. The transverse mesocolon covers the retroperitoneally located duodenum.

قطاعات عرضية في منطقة المعدة في مراحل جنينية مختلفة توضح الفضاء البريتوني

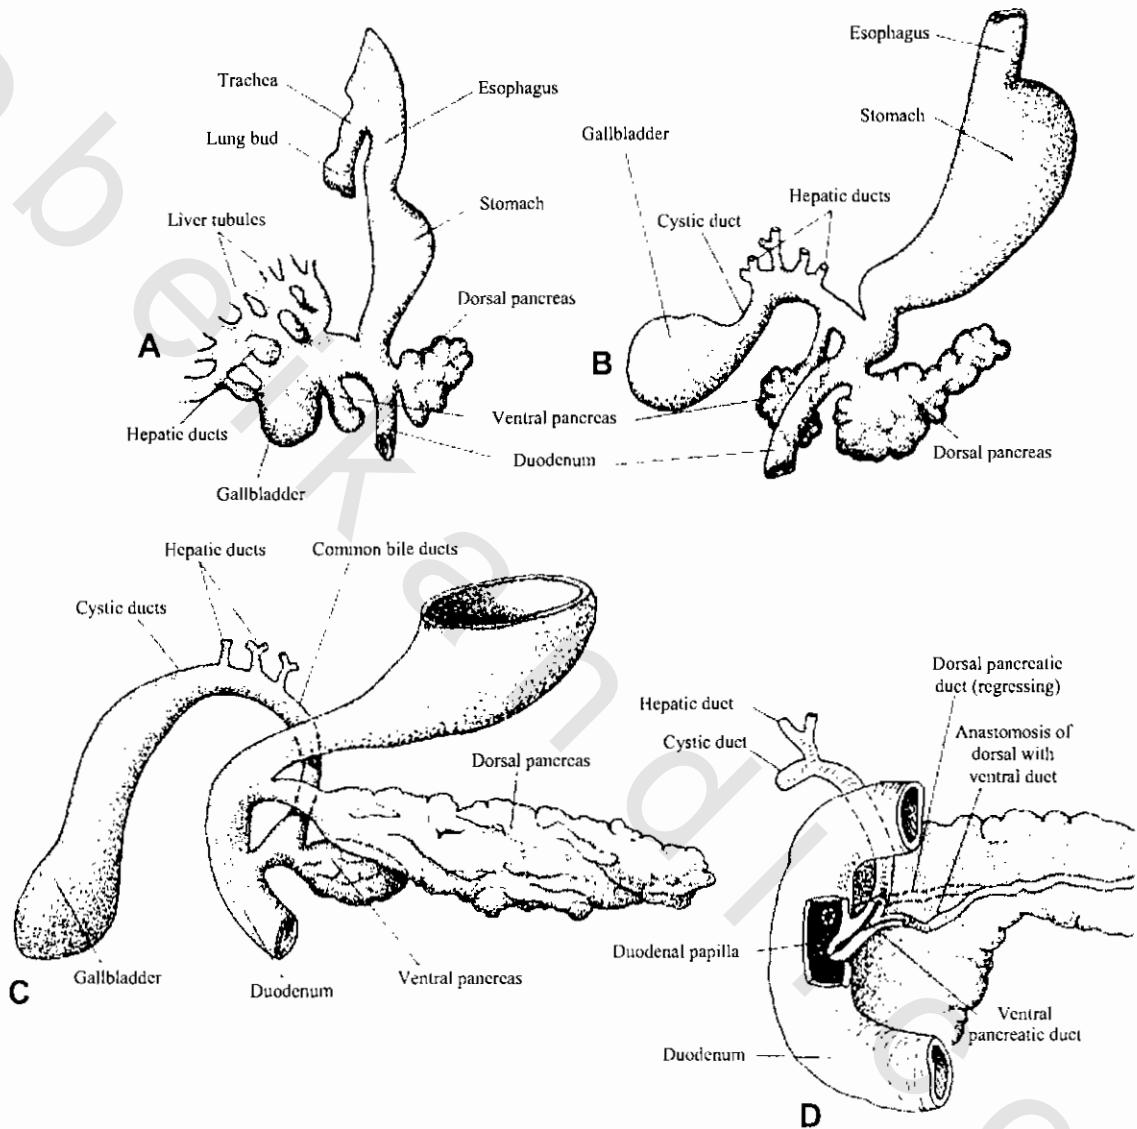

A, Drawing of the positions of the spleen, stomach, and pancreas at the end of the 5th week. Note the position of the spleen and pancreas in the dorsal mesogastrium. B, Position of spleen and stomach at the 11th week: Note the formation of the omental bursa or lesser peritoneal sac.

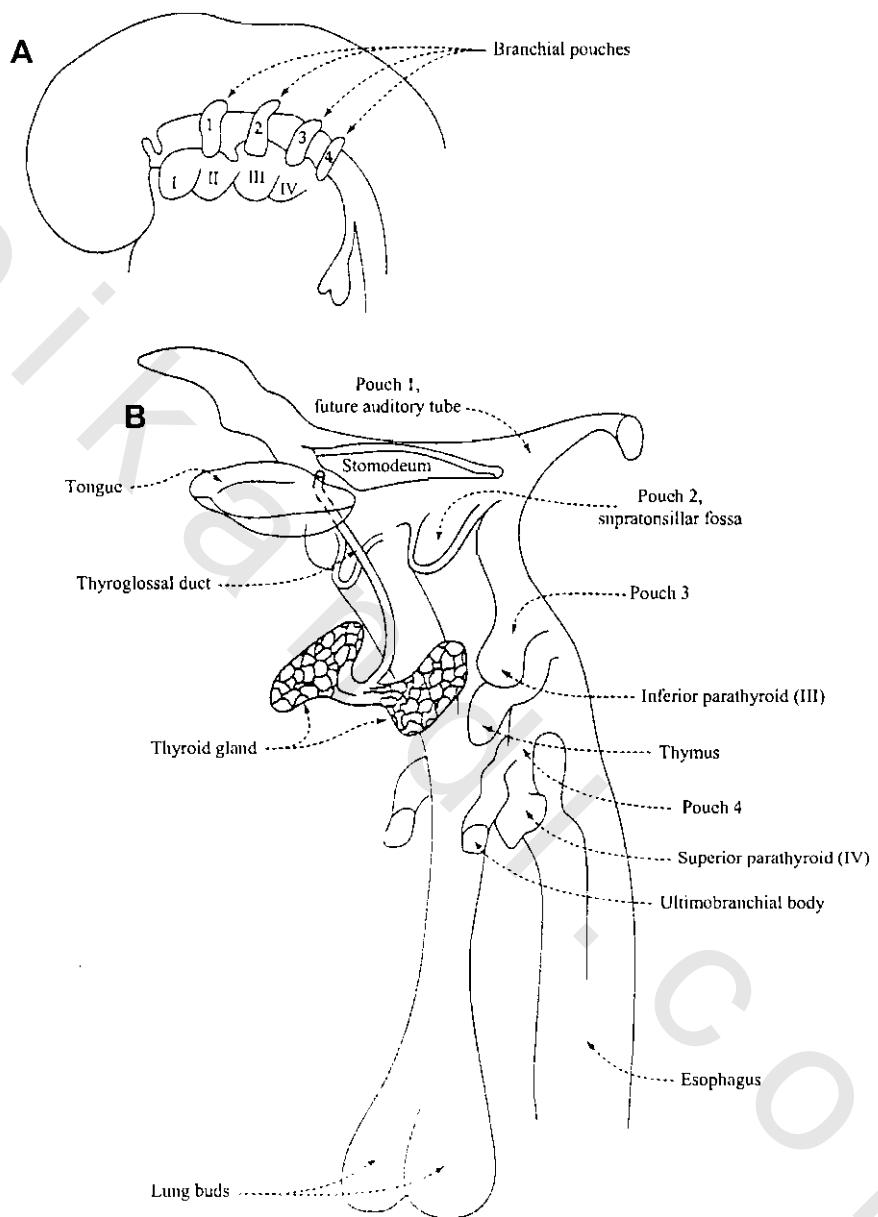

Diagrammatic transverse sections through the region of the stomach, liver, and spleen, showing the formation of the lesser peritoneal sac, the rotation of the stomach, and the position of the spleen and tail of the pancreas between the two leaves of the dorsal mesogastrium. With further development, the pancreas obtains a retroperitoneal position.

تكوين الكبد والبنكرياس في الإنسان

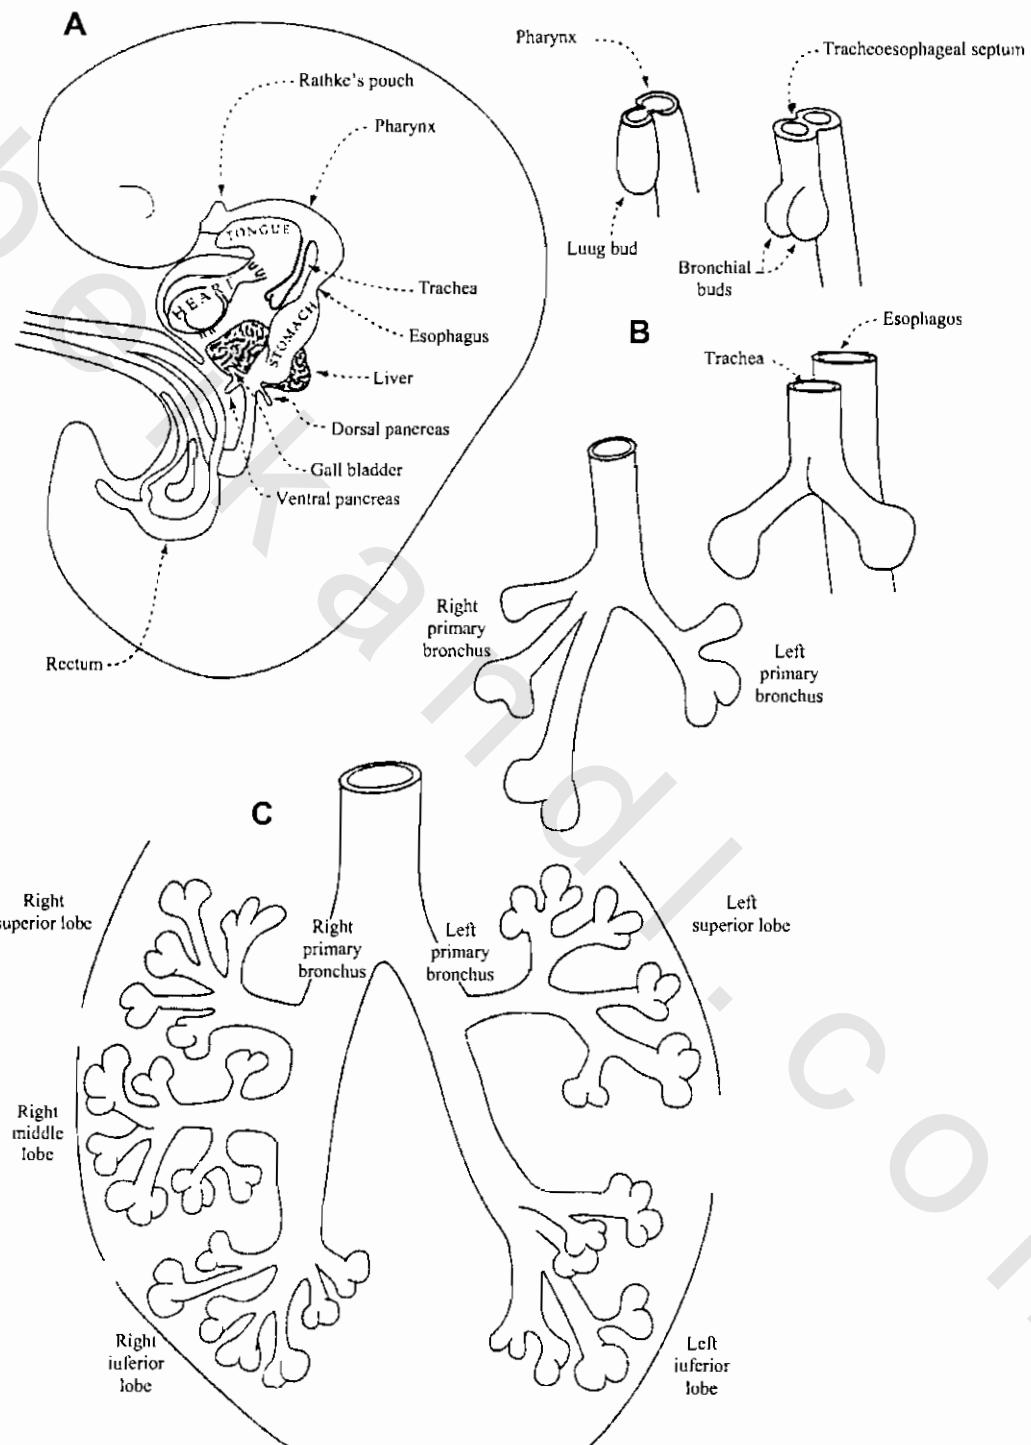

Development of hepatic and pancreatic primordia. All diagrams are viewed from the ventral aspect. (A) Semischematic diagram based in part on Thyng's reconstructions of a 5.5-mm pig embryo. This is comparable to a human embryo early in the fifth week. (B) Reconstruction from a 9.4-mm pig embryo. This is comparable to a human embryo of 7 weeks. (C) Schematized drawing equivalent to a 20-mm pig embryo or a human embryo of 7 weeks. (D) Manner in which common bile duct and pancreatic duct become confluent and discharge through the duodenal papilla.

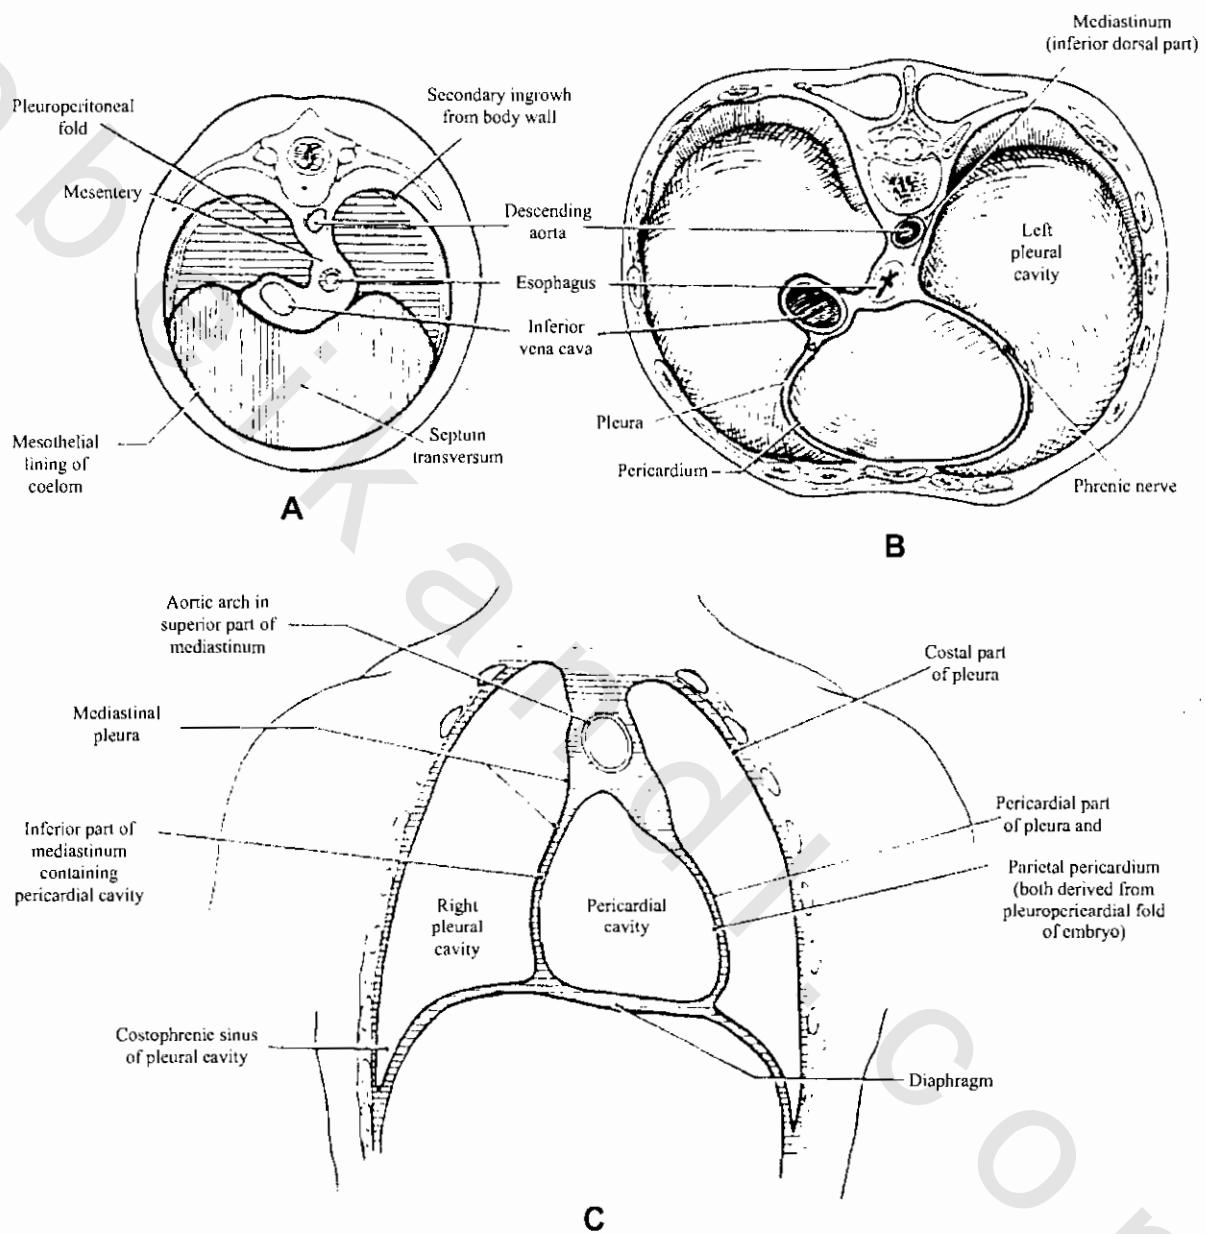

مناظر بطنية توضح تكوين الجهاز التنفسى فى مراحل مختلفة من أجنة خنزير

Development of the respiratory system of pig embryo

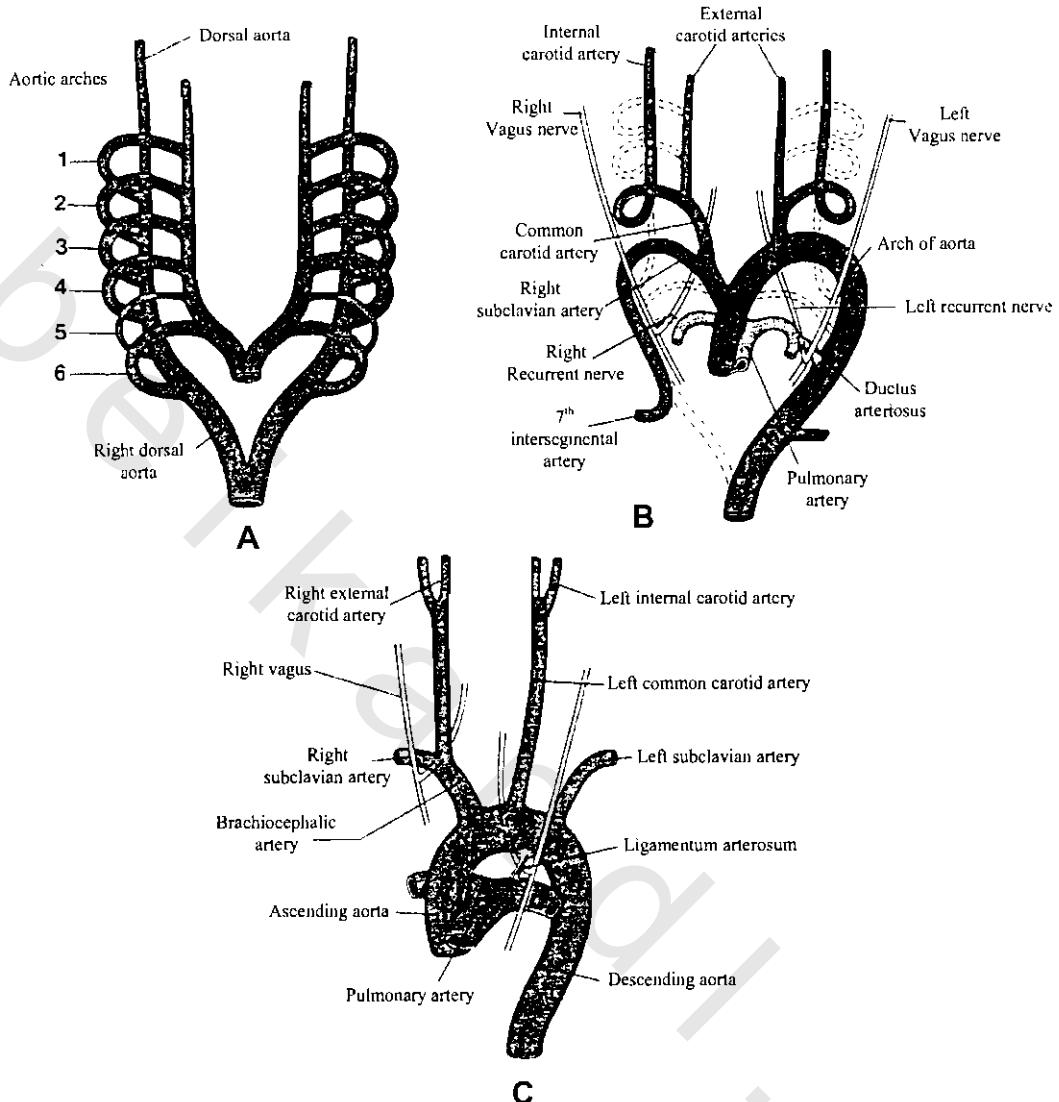

قطاعات عرضية ومنظر أمامي لمنطقة الحجاب الحاجز

Diaphragm in embryo and in adult. (A) Diagram indicating embryological origin of various regions of diaphragm. (Modified from Broman.) (B) Thoracic face of adult diaphragm. (Modified from Rauber-Kopsch.) (C) Relations of diaphragm as seen in a frontal section of adult body. (Modified from Rauber-Kopsch.)

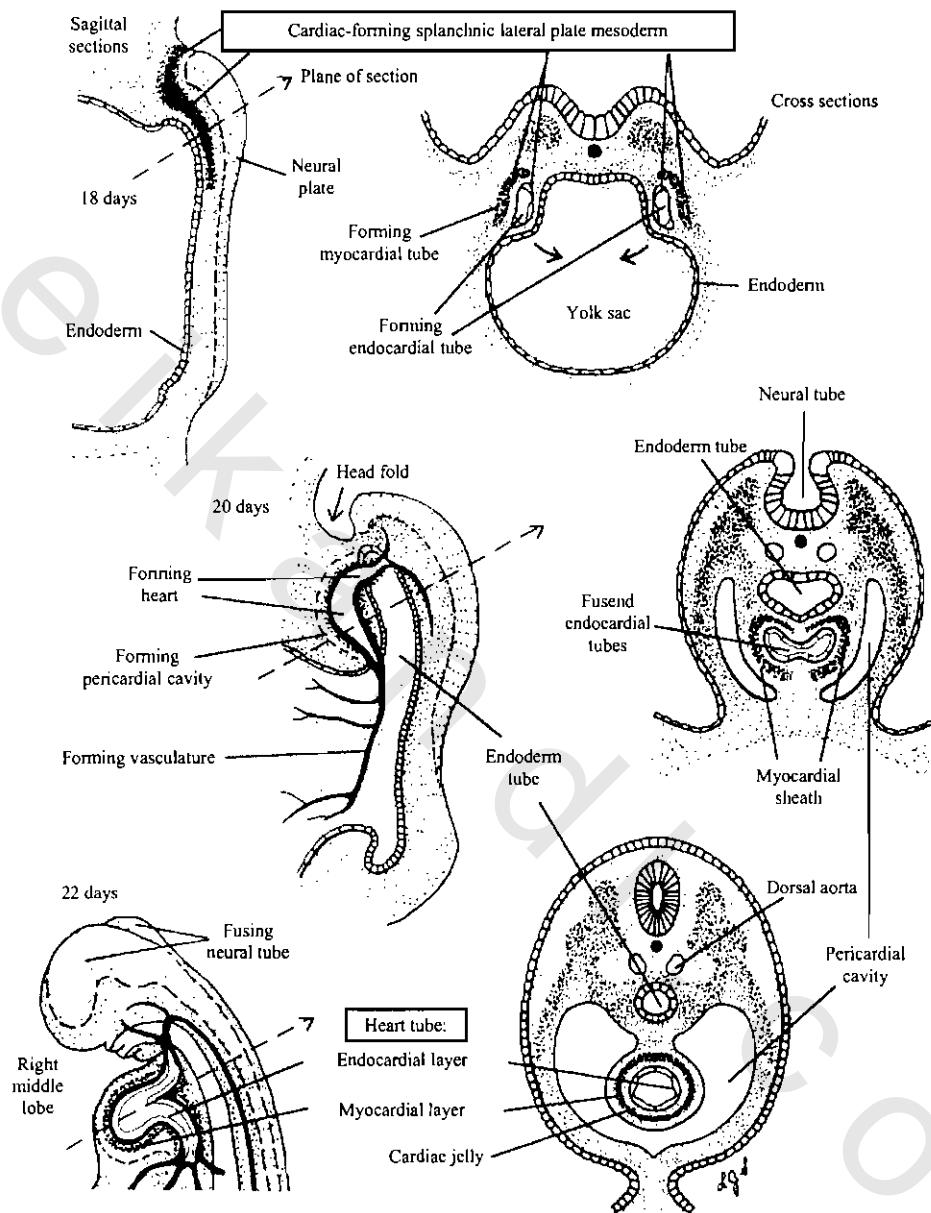

الأقواس الأورطية وتطورها إلى الشريانين الرئيسيين المحيطة بالقلب في الثدييات

A, Diagram of the aortic arches and dorsal aortas before transformation into the definitive vascular pattern. B, Diagram of the aortic arches and dorsal aortas after the transformation. The obliterated components are indicated by broken lines. Note the patent ductus arteriosus and the position of the seventh intersegmental artery on the left. C, The great arteries in the adult. Compare the distance between the place of origin of the left common carotid artery and the left subclavian in B and C. After disappearance of the distal part of the sixth aortic arch and the fifth arch on the right, the right recurrent laryngeal nerve hooks around the right subclavian artery. On the left the nerve remains in place and hooks around the ligamentum arteriosum.

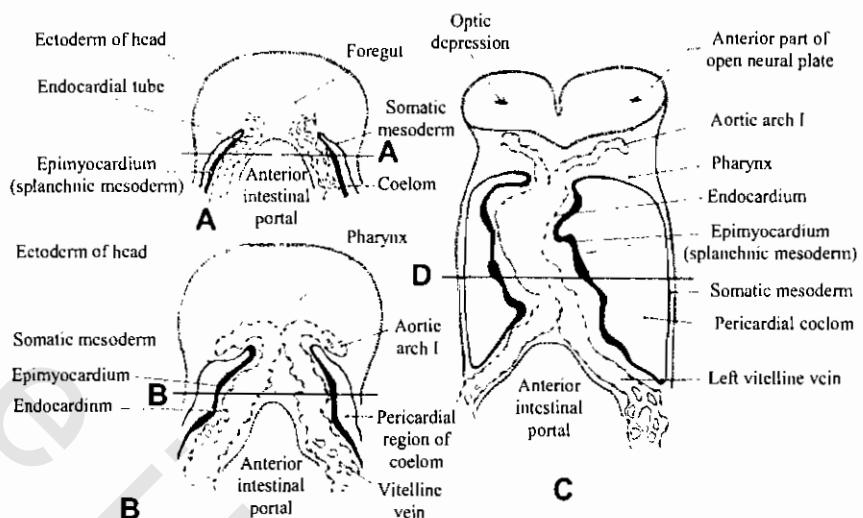

المراحل الأولية لتكوين أنابيب القلب في الإنسان

Formation and fusion of bilateral heart tubes

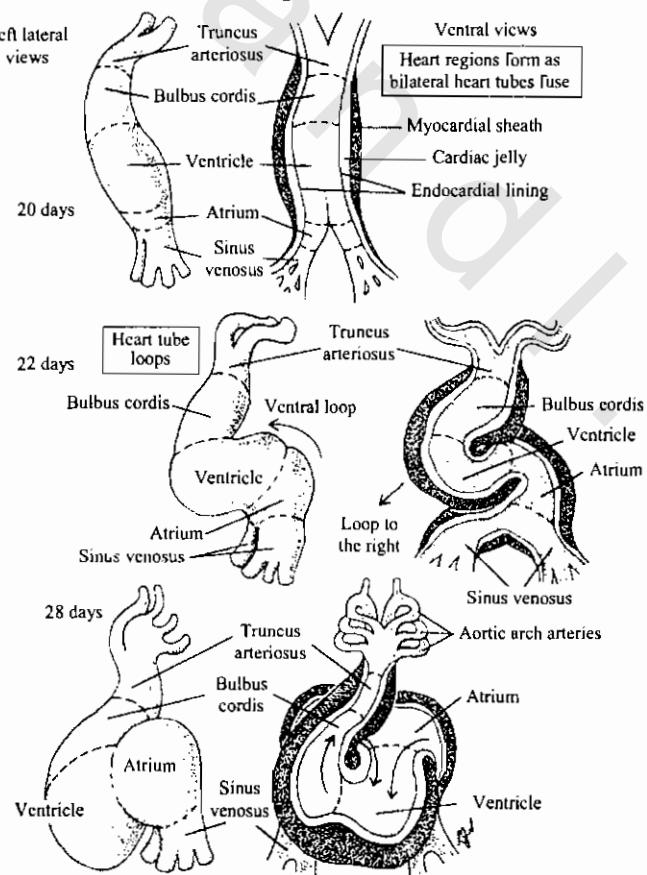

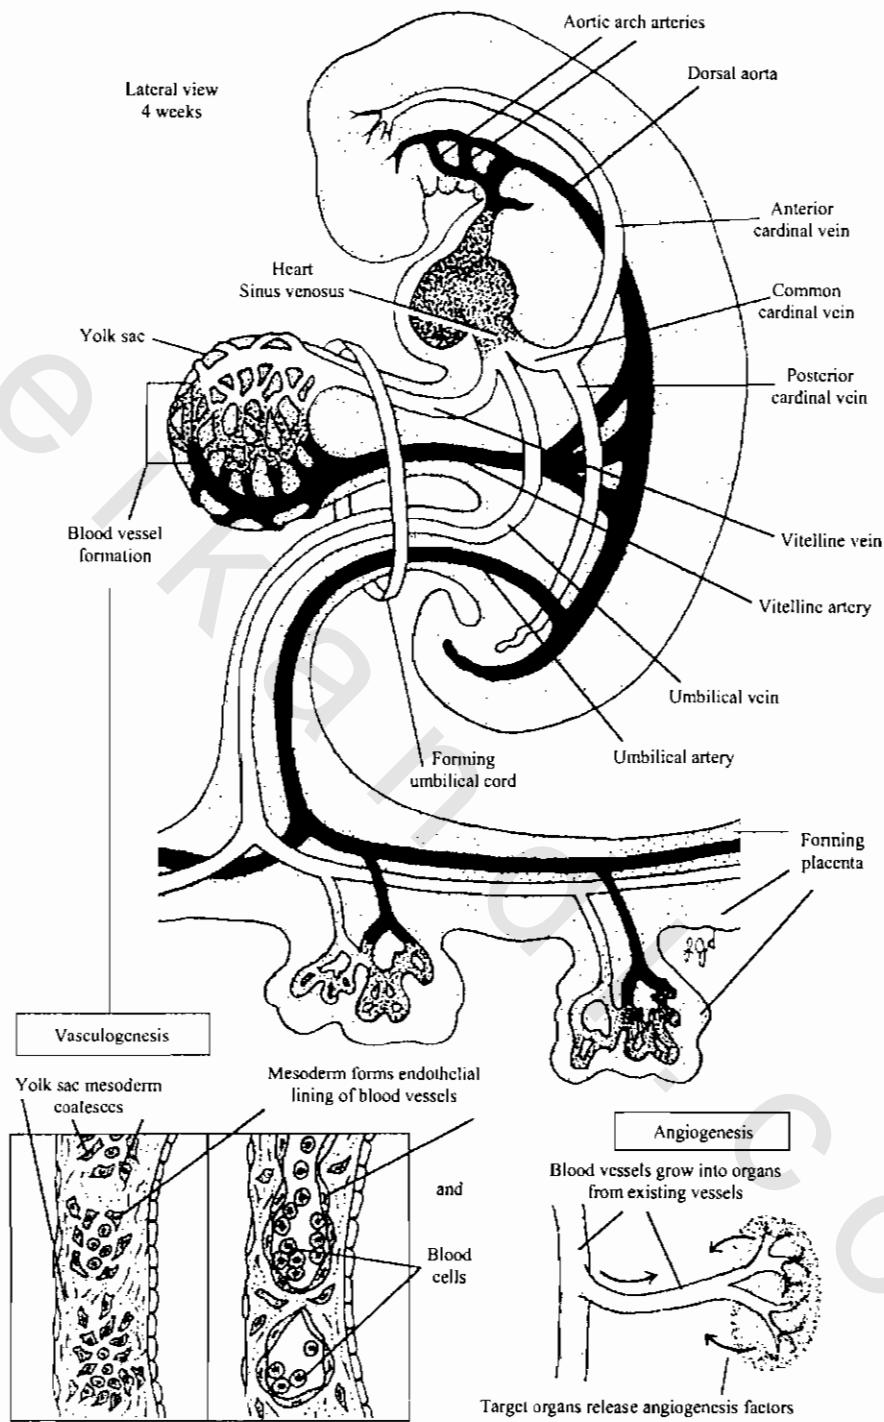

تكوين القلب وتميز حجراته المختلفة في الإنسان

الأحداث المواكبة للتبويض في الإنسان

The major events in human oogenesis

Age	Follicular histology	Meiotic events in ovum	Chromosomal complement
Fetal period	No follicle	Oogonium <i>Mitosis</i>	2N,2C
Before or at birth	Primordial follicle	Primary oocyte <i>Meiosis in progress</i>	2N,4C
After birth	Primordial follicle	Primary oocyte <i>Arrested in diplotene stage of first meiotic division</i>	2N,4C
After puberty	Secondary follicle	Primary oocyte <i>First meiotic division completed, start of second meiotic division</i>	2N,4C
	Tertiary follicle	Secondary oocyte + Polar body I <i>Ovulation</i>	1N,2C
	Ovulated ovum	Secondary oocyte + Polar body I <i>Arrested at metaphase I</i>	1N,2C
	Fertilized ovum	Fertilized ovum + Polar body II <i>Fertilization - second meiotic division completed</i>	1N,1C - sperm

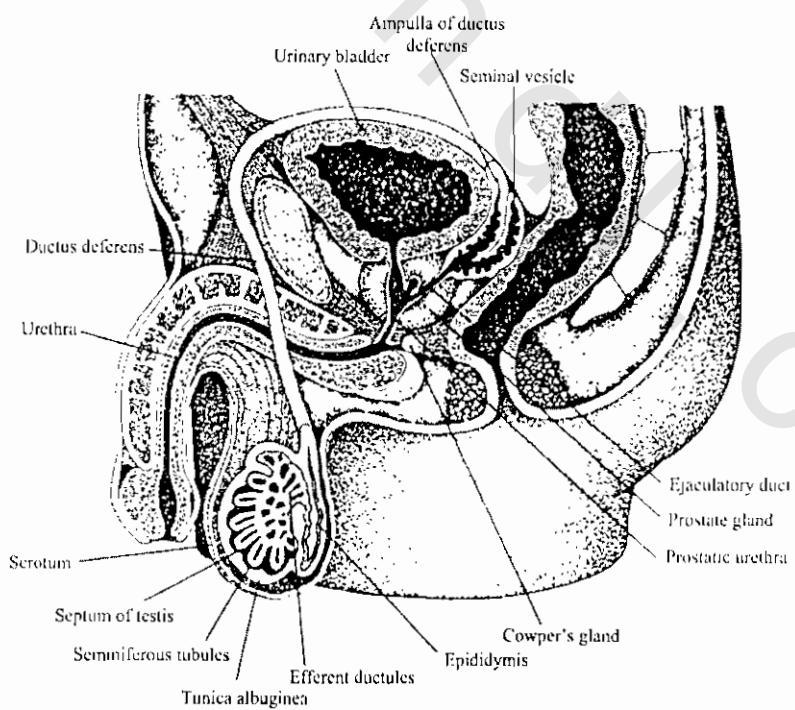

The diagram shows the progression of oogenesis through various stages:

- Fetal period:** Oogonium undergoes mitosis.
- Before or at birth:** Primordial follicle (Primary oocyte) undergoes meiosis in progress.
- After birth:** Primordial follicle (Primary oocyte) arrested in diplotene stage of first meiotic division.
- After puberty:** Secondary follicle (Primary oocyte) undergoes first meiotic division completed, starting the second meiotic division.
- Tertiary follicle:** Secondary oocyte + Polar body I. This stage is marked by ovulation.
- Ovulated ovum:** Secondary oocyte + Polar body I. The secondary oocyte is arrested at metaphase I.
- Fertilized ovum:** Fertilized ovum + Polar body II. The second meiotic division is completed, resulting in a fertilized ovum and a second polar body.

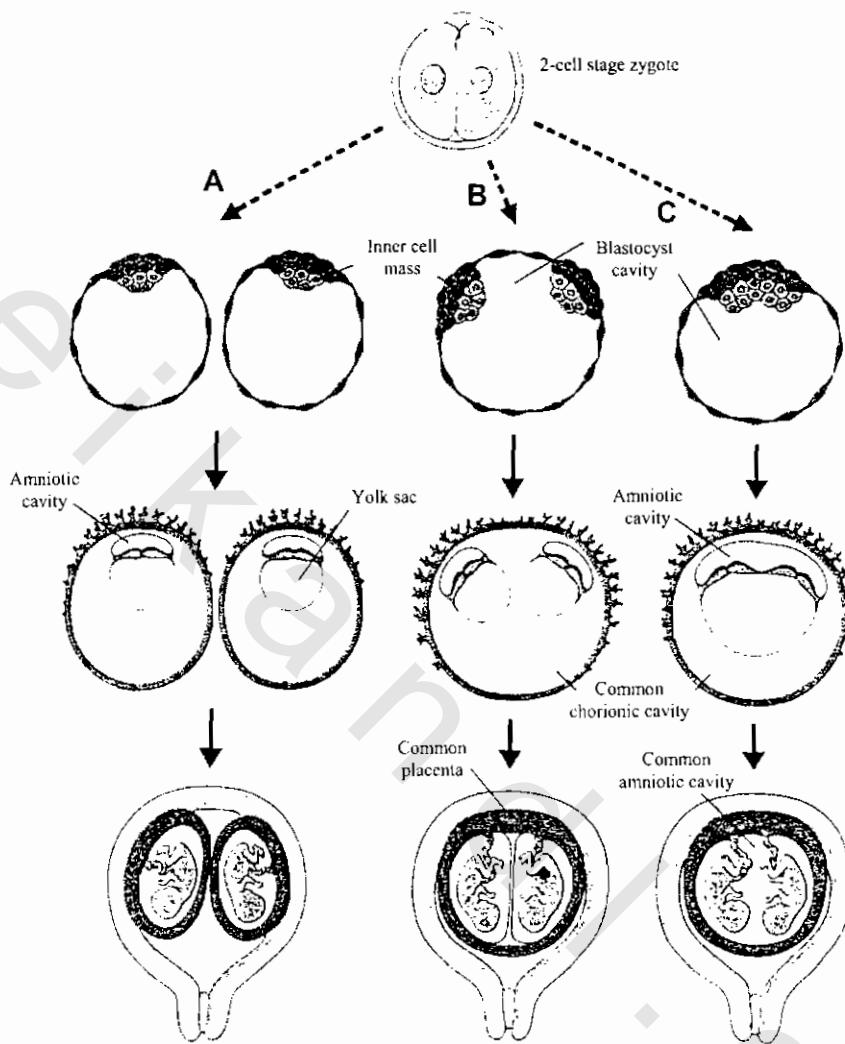

الجهاز التناسلي الأنثى

The female genital system

الجهاز التناسلي في الذكر

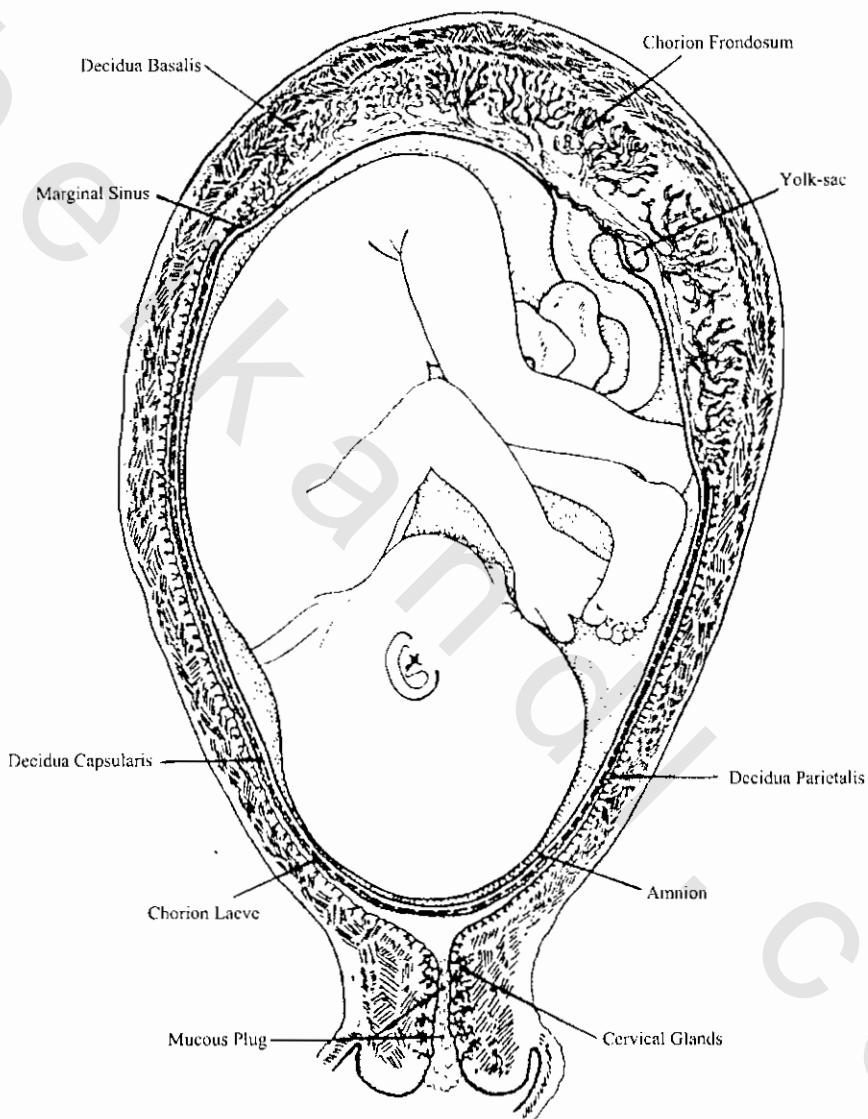

Male reproductive system

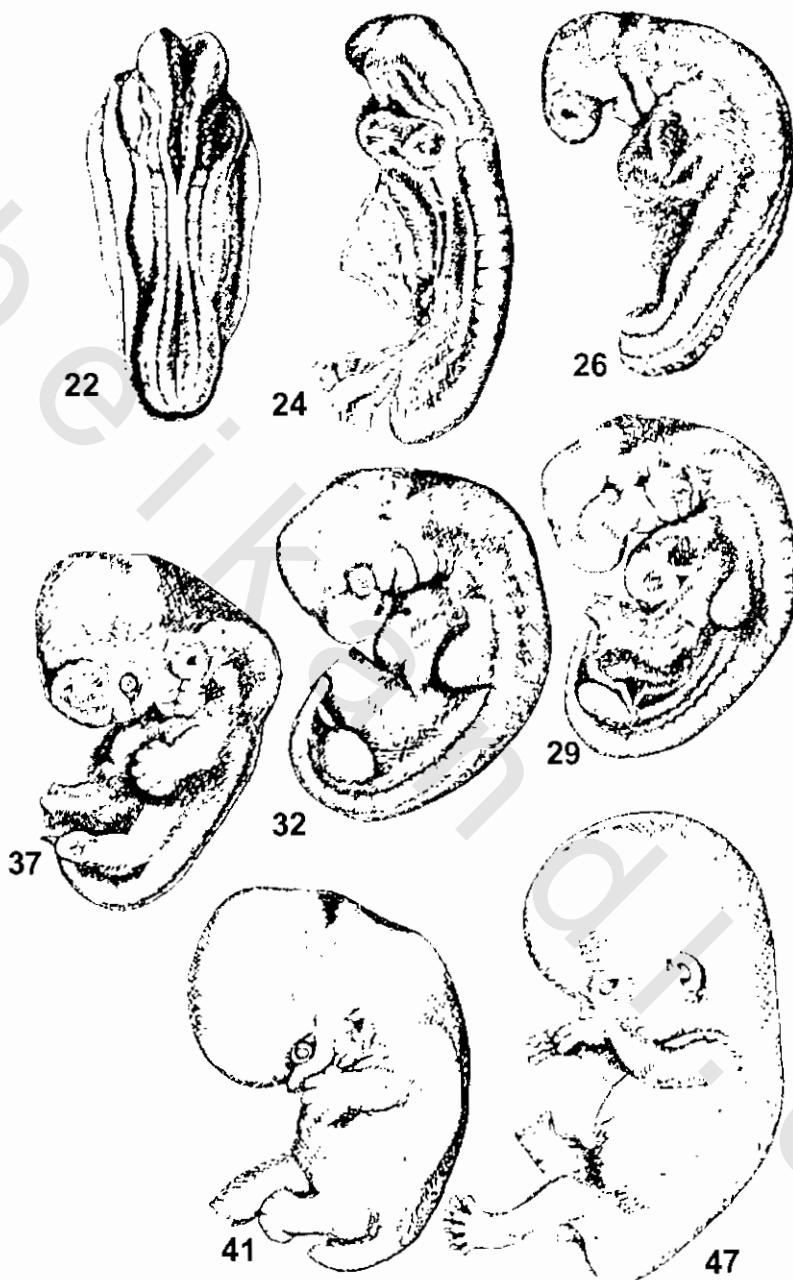

Schematic diagrams showing the possible relations of the fetal membranes in monozygotic twins.
 A, Splitting occurs at the two-cell stage and each embryo has its own placenta, amniotic cavity, and chorionic cavity. B, Splitting of the inner cell mass into two completely separated groups. The two embryos have a common placenta and a common chorionic sac, but separate amniotic cavities. C, Splitting of the inner cell mass at a late stage of development. The embryos have a common placenta, a common amniotic cavity, and a common chorionic cavity.

جنين الإنسان في عمر خمسة أشهر

5- Month human fetus

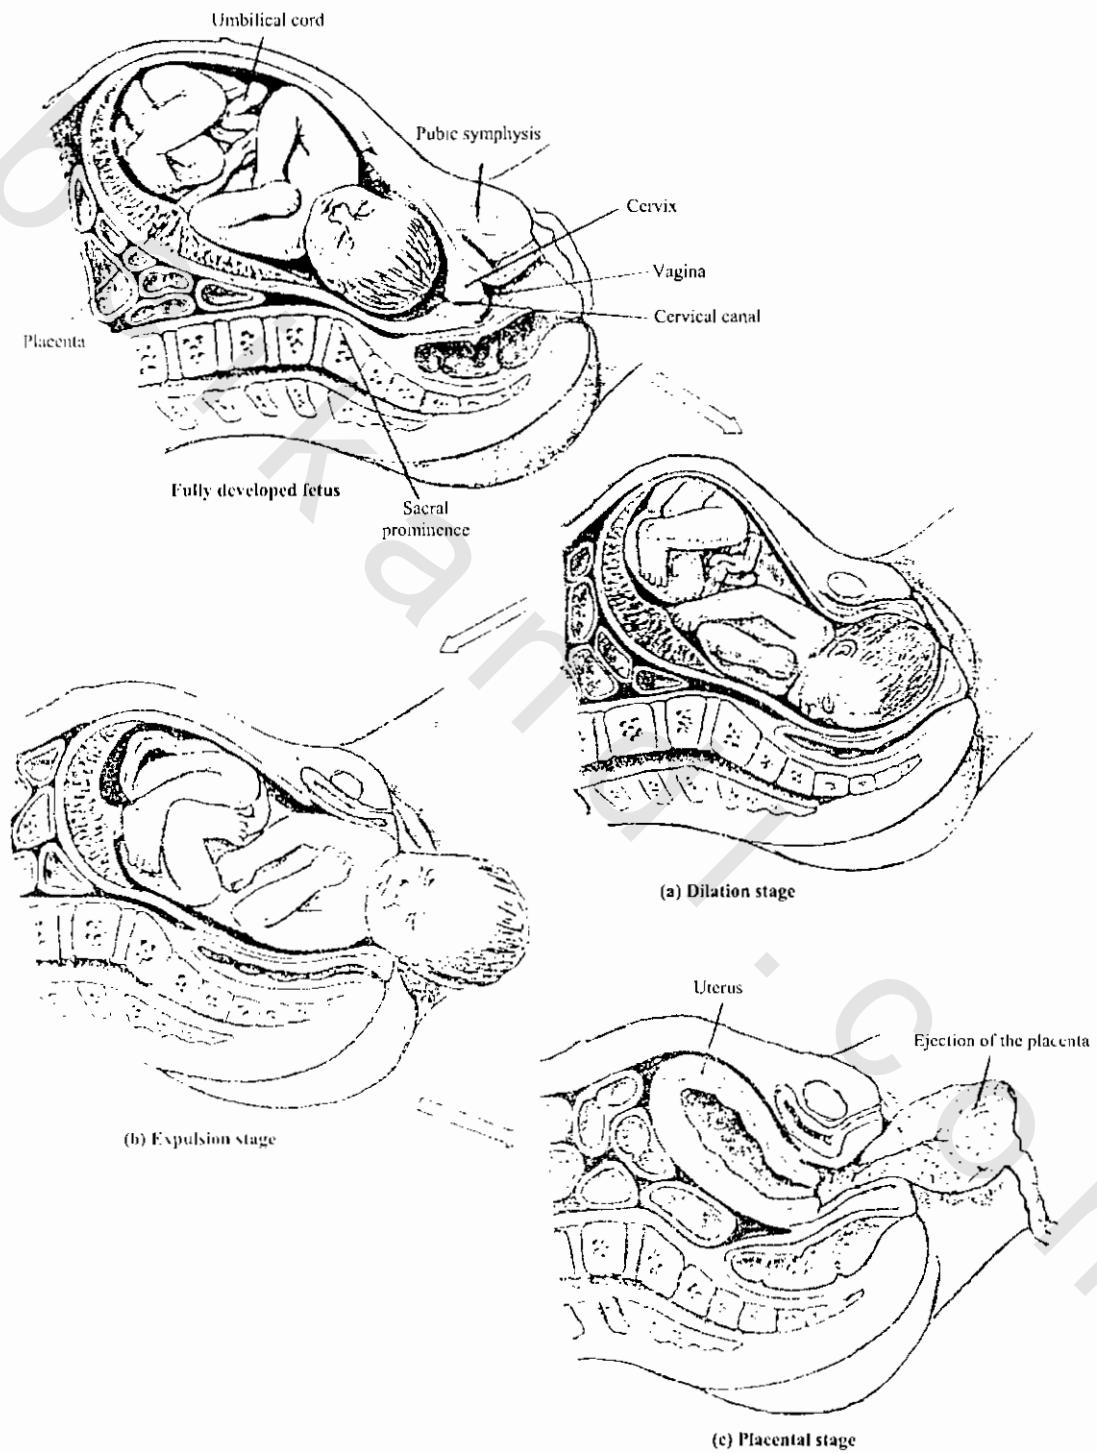

الشكل الخارجي لجنين إنسان في مراحل مختلفة من النمو

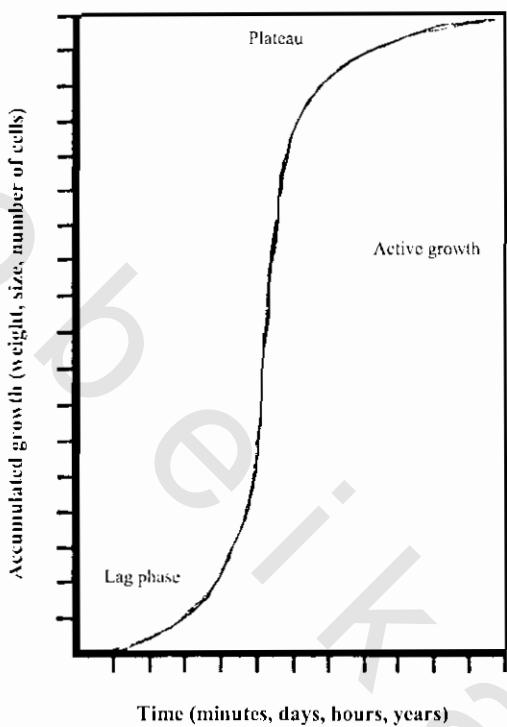

Stages of development of the human embryo. Figures show approximate age in days.(22-day-old embryo, after Arey: Developmental Anatomy; 37-day-old embryo redrawn from Hamilton, Boyd, and Mossman, 1947; the rest after Streeter, 1942 – 1951.)

مراحل الولادة

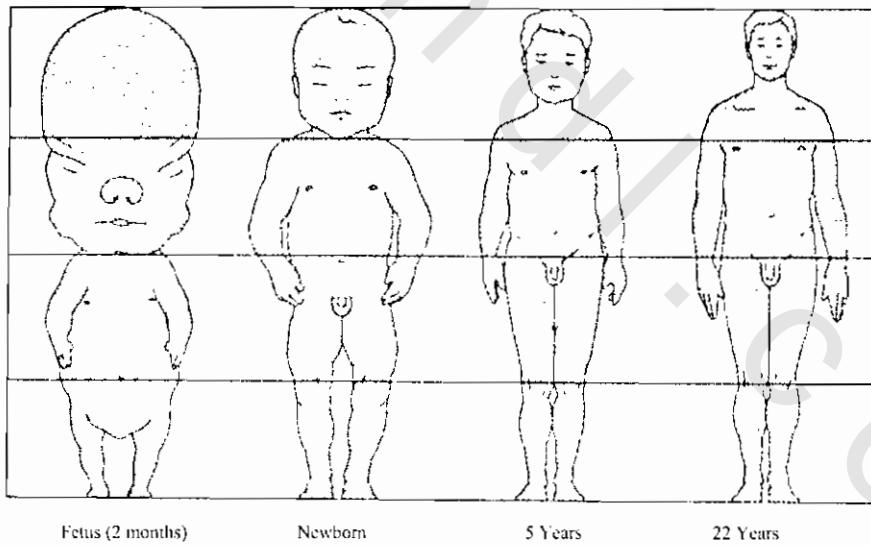

The Stages of Labor

منحنى النمو في الخلايا المزروعة أو في عدد الأفراد
أو المجتمع بمرور الوقت

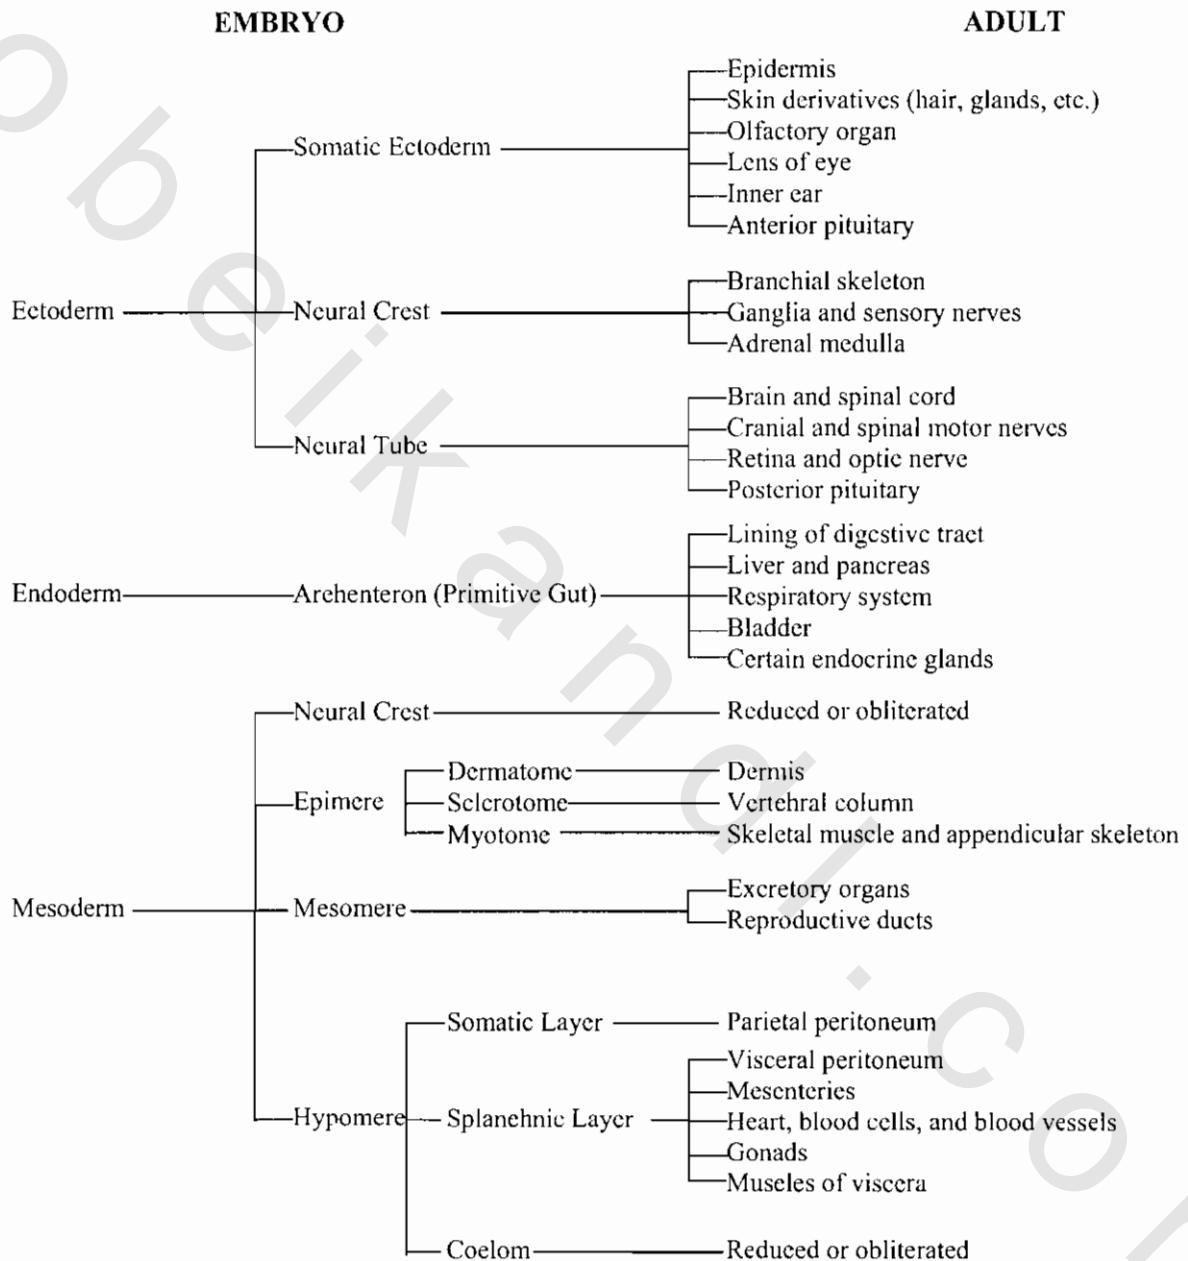

Growth curve of cells, organisms, or populations is shaped. The abscissa is an expression of time, and the ordinate is some measurement of growth. Growth starts out slowly, enters a period of rapid increase, and then reaches a plateau.

التغير في شكل جسم الإنسان أثناء نموه من جنين إلى فرد بالغ
Alterations in form of human body as it develops from embryo to adult.

الأعضاء المكونة من الثلاث طبقات الجنينية الأساسية

Chart showing the embryonic derivation of the principal parts of the adult body.
